## List of Registers

<b>System Control .....</b>	<b>90</b>
Register 1: Device Identification 0 (DID0), offset 0x000 .....	102
Register 2: Brown-Out Reset Control (PBORCTL), offset 0x030 .....	104
Register 3: Raw Interrupt Status (RIS), offset 0x050 .....	105
Register 4: Interrupt Mask Control (IMC), offset 0x054 .....	107
Register 5: Masked Interrupt Status and Clear (MISC), offset 0x058 .....	109
Register 6: Reset Cause (RESC), offset 0x05C .....	111
Register 7: Run-Mode Clock Configuration (RCC), offset 0x060 .....	113
Register 8: XTAL to PLL Translation (PLLCFG), offset 0x064 .....	118
Register 9: GPIO Host-Bus Control (GPIOHBCTL), offset 0x06C .....	119
Register 10: Run-Mode Clock Configuration 2 (RCC2), offset 0x070 .....	121
Register 11: Main Oscillator Control (MOSCCTL), offset 0x07C .....	124
Register 12: Deep Sleep Clock Configuration (DSLPCCLKCFG), offset 0x144 .....	125
Register 13: Deep Sleep Flash Configuration (DSFLASHCFG), offset 0x14C .....	127
Register 14: Precision Internal Oscillator Calibration (PIOSCCAL), offset 0x150 .....	128
Register 15: I <sup>2</sup> S MCLK Configuration (I2SMCLKCFG), offset 0x170 .....	129
Register 16: Device Identification 1 (DID1), offset 0x004 .....	131
Register 17: Device Capabilities 0 (DC0), offset 0x008 .....	133
Register 18: Device Capabilities 1 (DC1), offset 0x010 .....	134
Register 19: Device Capabilities 2 (DC2), offset 0x014 .....	137
Register 20: Device Capabilities 3 (DC3), offset 0x018 .....	140
Register 21: Device Capabilities 4 (DC4), offset 0x01C .....	143
Register 22: Device Capabilities 5 (DC5), offset 0x020 .....	145
Register 23: Device Capabilities 6 (DC6), offset 0x024 .....	147
Register 24: Device Capabilities 7 (DC7), offset 0x028 .....	148
Register 25: Device Capabilities 8 ADC Channels (DC8), offset 0x02C .....	152
Register 26: Device Capabilities 9 ADC Digital Comparators (DC9), offset 0x190 .....	155
Register 27: Non-Volatile Memory Information (NVMSTAT), offset 0x1A0 .....	157
Register 28: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100 .....	158
Register 29: Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110 .....	161
Register 30: Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120 .....	164
Register 31: Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104 .....	167
Register 32: Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114 .....	171
Register 33: Deep-Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124 .....	175
Register 34: Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108 .....	179
Register 35: Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118 .....	182
Register 36: Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128 .....	185
Register 37: Software Reset Control 0 (SRCR0), offset 0x040 .....	188
Register 38: Software Reset Control 1 (SRCR1), offset 0x044 .....	190
Register 39: Software Reset Control 2 (SRCR2), offset 0x048 .....	193
<b>Internal Memory .....</b>	<b>195</b>
Register 1: Flash Memory Address (FMA), offset 0x000 .....	201
Register 2: Flash Memory Data (FMD), offset 0x004 .....	202
Register 3: Flash Memory Control (FMC), offset 0x008 .....	203
Register 4: Flash Controller Raw Interrupt Status (FCRIS), offset 0x00C .....	205

Register 5:	Flash Controller Interrupt Mask (FCIM), offset 0x010 .....	206
Register 6:	Flash Controller Masked Interrupt Status and Clear (FCMISC), offset 0x014 .....	207
Register 7:	Flash Memory Control 2 (FMC2), offset 0x020 .....	208
Register 8:	Flash Write Buffer Valid (FWBVAL), offset 0x030 .....	209
Register 9:	Flash Write Buffer n (FWBn), offset 0x100 - 0x13C .....	210
Register 10:	ROM Control (RMCTL), offset 0x0F0 .....	211
Register 11:	ROM Version Register (RMVER), offset 0x0F4 .....	212
Register 12:	Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200 .....	213
Register 13:	Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400 .....	214
Register 14:	User Debug (USER_DBG), offset 0x1D0 .....	215
Register 15:	User Register 0 (USER_REG0), offset 0x1E0 .....	216
Register 16:	User Register 1 (USER_REG1), offset 0x1E4 .....	217
Register 17:	User Register 2 (USER_REG2), offset 0x1E8 .....	218
Register 18:	User Register 3 (USER_REG3), offset 0x1EC .....	219
Register 19:	Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204 .....	220
Register 20:	Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208 .....	221
Register 21:	Flash Memory Protection Read Enable 3 (FMPRE3), offset 0x20C .....	222
Register 22:	Flash Memory Protection Program Enable 1 (FMPPE1), offset 0x404 .....	223
Register 23:	Flash Memory Protection Program Enable 2 (FMPPE2), offset 0x408 .....	224
Register 24:	Flash Memory Protection Program Enable 3 (FMPPE3), offset 0x40C .....	225
<b>Micro Direct Memory Access (μDMA) .....</b>		<b>226</b>
Register 1:	DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000 .....	249
Register 2:	DMA Channel Destination Address End Pointer (DMADSTENDP), offset 0x004 .....	250
Register 3:	DMA Channel Control Word (DMACHCTL), offset 0x008 .....	251
Register 4:	DMA Status (DMASTAT), offset 0x000 .....	256
Register 5:	DMA Configuration (DMACFG), offset 0x004 .....	258
Register 6:	DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008 .....	259
Register 7:	DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C .....	260
Register 8:	DMA Channel Wait-on-Request Status (DMAWAITSTAT), offset 0x010 .....	261
Register 9:	DMA Channel Software Request (DMASWREQ), offset 0x014 .....	262
Register 10:	DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018 .....	263
Register 11:	DMA Channel Useburst Clear (DMAUSEBURSTCLR), offset 0x01C .....	265
Register 12:	DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020 .....	266
Register 13:	DMA Channel Request Mask Clear (DMAREQMASKCLR), offset 0x024 .....	268
Register 14:	DMA Channel Enable Set (DMAENASET), offset 0x028 .....	269
Register 15:	DMA Channel Enable Clear (DMAENACL), offset 0x02C .....	271
Register 16:	DMA Channel Primary Alternate Set (DMAALTSET), offset 0x030 .....	272
Register 17:	DMA Channel Primary Alternate Clear (DMAALTCLR), offset 0x034 .....	274
Register 18:	DMA Channel Priority Set (DMAPRIOSET), offset 0x038 .....	275
Register 19:	DMA Channel Priority Clear (DMAPRIOCLR), offset 0x03C .....	277
Register 20:	DMA Bus Error Clear (DMAERRCLR), offset 0x04C .....	278
Register 21:	DMA Channel Alternate Select (DMACHALT), offset 0x500 .....	280
Register 22:	DMA Channel Interrupt Status (DMACHIS), offset 0x504 .....	281
Register 23:	DMA Peripheral Identification 0 (DMAPeriphID0), offset 0xFE0 .....	282
Register 24:	DMA Peripheral Identification 1 (DMAPeriphID1), offset 0xFE4 .....	283
Register 25:	DMA Peripheral Identification 2 (DMAPeriphID2), offset 0xFE8 .....	284
Register 26:	DMA Peripheral Identification 3 (DMAPeriphID3), offset 0xFEC .....	285
Register 27:	DMA Peripheral Identification 4 (DMAPeriphID4), offset 0xFD0 .....	286

Register 28:	DMA PrimeCell Identification 0 (DMAPCellID0), offset 0xFF0 .....	287
Register 29:	DMA PrimeCell Identification 1 (DMAPCellID1), offset 0xFF4 .....	288
Register 30:	DMA PrimeCell Identification 2 (DMAPCellID2), offset 0xFF8 .....	289
Register 31:	DMA PrimeCell Identification 3 (DMAPCellID3), offset 0xFFC .....	290
<b>General-Purpose Input/Outputs (GPIOs) .....</b>		<b>291</b>
Register 1:	GPIO Data (GPIODATA), offset 0x000 .....	301
Register 2:	GPIO Direction (GPIODIR), offset 0x400 .....	302
Register 3:	GPIO Interrupt Sense (GPIOIS), offset 0x404 .....	303
Register 4:	GPIO Interrupt Both Edges (GPIOIBE), offset 0x408 .....	304
Register 5:	GPIO Interrupt Event (GPIOIEV), offset 0x40C .....	305
Register 6:	GPIO Interrupt Mask (GPIOIM), offset 0x410 .....	306
Register 7:	GPIO Raw Interrupt Status (GPIORIS), offset 0x414 .....	307
Register 8:	GPIO Masked Interrupt Status (GPIOMIS), offset 0x418 .....	308
Register 9:	GPIO Interrupt Clear (GPIOICR), offset 0x41C .....	310
Register 10:	GPIO Alternate Function Select (GPIOAFSEL), offset 0x420 .....	311
Register 11:	GPIO 2-mA Drive Select (GPIODR2R), offset 0x500 .....	313
Register 12:	GPIO 4-mA Drive Select (GPIODR4R), offset 0x504 .....	314
Register 13:	GPIO 8-mA Drive Select (GPIODR8R), offset 0x508 .....	315
Register 14:	GPIO Open Drain Select (GPIOODR), offset 0x50C .....	316
Register 15:	GPIO Pull-Up Select (GPIOPUR), offset 0x510 .....	317
Register 16:	GPIO Pull-Down Select (GPIOPDR), offset 0x514 .....	319

## About This Document

This data sheet provides reference information for the LM3S9792 microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M3 core.

### Audience

This manual is intended for system software developers, hardware designers, and application developers.

### About This Manual

This document is organized into sections that correspond to each major feature.

### Related Documents

The following documents are referenced by the data sheet, and available on the documentation CD or from the Luminary Micro web site at [www.luminarymicro.com](http://www.luminarymicro.com):

- *ARM® Cortex™-M3 Technical Reference Manual*
- *ARM® CoreSight Technical Reference Manual*
- *ARM® v7-M Architecture Application Level Reference Manual*
- *Stellaris® Peripheral Driver Library User's Guide*
- *Stellaris® ROM User's Guide*

The following related documents are also referenced:

- *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*

This documentation list was current as of publication date. Please check the Luminary Micro web site for additional documentation, including application notes and white papers.

### Documentation Conventions

This document uses the conventions shown in Table 1 on page 31.

**Table 1. Documentation Conventions**

Notation	Meaning
<b>General Register Notation</b>	
<b>REGISTER</b>	APB registers are indicated in uppercase bold. For example, <b>PBORCTL</b> is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, <b>SRCRn</b> represents any (or all) of the three Software Reset Control registers: <b>SRCR0</b> , <b>SRCR1</b> , and <b>SRCR2</b> .
bit	A single bit in a register.
bit field	Two or more consecutive and related bits.
offset 0xnnn	A hexadecimal increment to a register's address, relative to that module's base address as specified in "Memory Map" on page 72.

Notation	Meaning
Register <i>N</i>	Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.
reserved	Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
yy:xx	The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.
<b>Register Bit/Field Types</b>	This value in the register bit diagram indicates whether software running on the controller can change the value of the bit field.
RC	Software can read this field. The bit or field is cleared by hardware after reading the bit/field.
RO	Software can read this field. Always write the chip reset value.
R/W	Software can read or write this field.
R/W1C	Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged.  This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read.
R/W1S	Software can read or write a 1 to this field. A write of a 0 to a R/W1S bit does not affect the bit value in the register.
W1C	Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data.  This register is typically used to clear the corresponding bit in an interrupt register.
WO	Only a write by software is valid; a read of the register returns no meaningful data.
<b>Register Bit/Field Reset Value</b>	This value in the register bit diagram shows the bit/field value after any reset, unless noted.
0	Bit cleared to 0 on chip reset.
1	Bit set to 1 on chip reset.
-	Nondeterministic.
<b>Pin/Signal Notation</b>	
[ ]	Pin alternate function; a pin defaults to the signal without the brackets.
pin	Refers to the physical connection on the package.
signal	Refers to the electrical signal encoding of a pin.
assert a signal	Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see <code>SIGNAL</code> and <code>̄SIGNAL</code> below).
deassert a signal	Change the value of the signal from the logically True state to the logically False state.
<code>̄SIGNAL</code>	Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert <code>̄SIGNAL</code> is to drive it Low; to deassert <code>̄SIGNAL</code> is to drive it High.
<code>SIGNAL</code>	Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert <code>SIGNAL</code> is to drive it High; to deassert <code>SIGNAL</code> is to drive it Low.
<b>Numbers</b>	
X	An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.

Notation	Meaning
0x	Hexadecimal numbers have a prefix of 0x. For example, 0x00FF is the hexadecimal number FF.  All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.

# 1 Architectural Overview

Luminary Micro is the industry leader in bringing 32-bit capabilities and the full benefits of ARM® Cortex-M3™-based microcontrollers to the broadest reach of the microcontroller market. For current users of 8- and 16-bit MCUs, Stellaris® with Cortex-M3 offers a direct path to the strongest ecosystem of development tools, software and knowledge in the industry. Designers who migrate to Stellaris® benefit from great tools, small code footprint and outstanding performance. Even more important, designers can enter the ARM ecosystem with full confidence in a compatible roadmap from \$1 to 1 GHz. For users of current 32-bit MCUs, the Stellaris® family offers the industry's first implementation of Cortex-M3 and the Thumb-2 instruction set. With blazingly-fast responsiveness, Thumb-2 technology combines both 16-bit and 32-bit instructions to deliver the best balance of code density and performance. Thumb-2 uses 26 percent less memory than pure 32-bit code to reduce system cost while delivering 25 percent better performance. The Luminary Micro Stellaris® family of microcontrollers—the first ARM® Cortex™-M3 based controllers—brings high-performance 32-bit computing to cost-sensitive embedded microcontroller applications. These pioneering parts deliver customers 32-bit performance at a cost equivalent to legacy 8- and 16-bit devices, all in a package with a small footprint.

The LM3S9792 microcontroller has the following features:

- ARM® Cortex™-M3 Processor Core
  - 80-MHz operation; 100 DMIPS performance
  - ARM Cortex SysTick Timer
  - Nested Vectored Interrupt Controller (NVIC)
- On-Chip Memory
  - 128 KB single-cycle Flash
  - 64 KB single-cycle SRAM
  - Internal ROM loaded with StellarisWare software:
    - Stellaris® Peripheral Driver Library
    - Stellaris® Boot Loader
    - Advanced Encryption Standard (AES) cryptography tables
    - Cyclic Redundancy Check (CRC) error detection functionality
- External Peripheral Interface (EPI)
  - 8/16/32-bit dedicated parallel bus for external peripherals
  - Supports SDRAM, SRAM/Flash, FPGAs, CPLDs
- Advanced Serial Integration
  - 10/100 Ethernet MAC and PHY
  - Two CAN 2.0 A/B controllers

- USB 2.0 OTG/Host/Device
- Three UARTs with IrDA and ISO 7816 support (one UART with full modem controls)
- Two I<sup>2</sup>C modules
- Two Synchronous Serial Interface modules (SSI)
- Integrated Interchip Sound (I<sup>2</sup>S) module
- System Integration
  - Direct Memory Access Controller (DMA)
  - System control and clocks including on-chip precision 16-MHz oscillator
  - Four 32-bit timers (up to eight 16-bit)
  - Eight Capture Compare PWM pins (CCP)
  - Real-Time Clock
  - Two Watchdog Timers
    - One timer runs off the main oscillator
    - One timer runs off the precision internal oscillator
  - 0-65 GPIOs, depending on configuration
    - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
    - Independently configurable to 2, 4 or 8 mA drive capability
    - Up to 4 GPIOs can have 18 mA drive capability
- Advanced Motion Control
  - Eight advanced PWM outputs for motion and energy applications
  - Four fault inputs to promote low-latency shutdown
  - Two Quadrature Encoder Inputs (QEI)
- Analog
  - Two 10-bit Analog-to-Digital Converters (ADC) with sixteen analog input channels and sample rate of one million samples/second
  - Three Analog Comparators
  - 16 Digital Comparators
  - On-chip voltage regulator
- JTAG and ARM Serial Wire Debug (SWD)

- 100-pin LQFP package
- Industrial (-40°C to 85°C) Temperature Range

The LM3S9792 microcontroller is targeted for industrial applications, including remote monitoring, electronic point-of-sale machines, test and measurement equipment, network appliances and switches, factory automation, HVAC and building control, gaming equipment, motion control, medical instrumentation, and fire and security.

In addition, the LM3S9792 microcontroller offers the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure IP applications, and a large user community. Additionally, the microcontroller uses ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the LM3S9792 microcontroller is code-compatible to all members of the extensive Stellaris® family; providing flexibility to fit our customers' precise needs.

Luminary Micro offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network. See "Ordering and Contact Information" on page 1085 for ordering information for Stellaris® family devices.

## 1.1 Functional Overview

The following sections provide an overview of the features of the LM3S9792 microcontroller. The page number in parentheses indicates where that feature is discussed in detail. Ordering and support information can be found in "Ordering and Contact Information" on page 1085.

### 1.1.1 ARM Cortex™-M3

The following sections provide an overview of the ARM Cortex™-M3 processor core and instruction set, the integrated System Timer (SysTick) and the Nested Vectored Interrupt Controller.

#### 1.1.1.1 Processor Core (see page 59)

All members of the Stellaris® product family, including the LM3S9792 microcontroller, are designed around an ARM Cortex™-M3 processor core. The ARM Cortex-M3 processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

- 32-bit ARM® Cortex™-M3 v7M architecture optimized for small-footprint embedded applications
- Thumb-2 mixed 16-/32-bit instruction set, delivers the high performance expected of from a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices; typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- Harvard architecture characterized by separate buses for instruction and data

- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash usage
- 80-MHz operation
- 1.25 DMIPS/MHz

“ARM Cortex-M3 Processor Core” on page 59 provides an overview of the ARM core; the core is detailed in the *ARM® Cortex™-M3 Technical Reference Manual*.

#### 1.1.1.2 System Timer (SysTick) (see page 69)

ARM Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit, clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter
- A simple counter used to measure time to completion and time used
- An internal clock-source control based on missing/meeting durations. The COUNTFLAG field in the SysTick Control and Status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop

#### 1.1.1.3 Nested Vectored Interrupt Controller (NVIC) (see page 75)

The LM3S9792 controller includes the ARM Nested Vectored Interrupt Controller (NVIC). The NVIC and Cortex-M3 prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The interrupt vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, meaning that back-to-back interrupts can be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 53 interrupts.

- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications
- Dynamically reprioritizable interrupts
- Exceptional interrupt handling via hardware implementation of required register manipulations

“Interrupts” on page 75 provides an overview of the NVIC controller and the interrupt map. Exceptions and interrupts are detailed in the *ARM® Cortex™-M3 Technical Reference Manual*.

## 1.1.2 On-Chip Memory

The following sections describe the on-chip memory modules.

### 1.1.2.1 SRAM (see page 196)

The LM3S9792 microcontroller provides 64 KB of single-cycle on-chip SRAM. The internal SRAM of the Stellaris<sup>®</sup> devices is located at offset 0x2000.0000 of the device memory map.

Because read-modify-write (RMW) operations are very time consuming, ARM has introduced *bit-banding* technology in the new Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

Data can be transferred to and from the SRAM using the Micro Direct Memory Access Controller ( $\mu$ DMA).

### 1.1.2.2 Flash (see page 196)

The LM3S9792 microcontroller provides 128 KB of single-cycle on-chip Flash memory. The Flash is organized as a set of 2-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. These blocks are paired into a set of 2-KB blocks that can be individually protected. The blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

### 1.1.2.3 ROM (see page 1027)

Preprogrammed in the LM3S9792 microcontroller's on-chip read-only memory (ROM) is the Stellaris<sup>®</sup> Peripheral Driver Library, a royalty-free software library for controlling on-chip peripherals with a boot-loader capability. The library performs both peripheral initialization and control functions, with a choice of polled or interrupt-driven peripheral support. In addition, the library is designed to take full advantage of the stellar interrupt performance of the ARM<sup>®</sup> Cortex<sup>™</sup>-M3 core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free Stellaris<sup>®</sup> Boot Loader can act as an application loader and support in-field firmware updates.

The Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. AES is a strong encryption method with reasonable performance and size. In addition, it is fast in both hardware and software, is fairly easy to implement, and requires little memory. The Luminary Micro encryption package is available with full source code, and is based on lesser general public license (LGPL) source. An LGPL means that the code can be used within an application without any copyleft implications for the application (the code does not automatically become open source). Modifications to the package source, however, must be open source.

CRC (Cyclic Redundancy Check) is a technique to validate a span of data has the same contents as when previously checked. This technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily.

The LM3S9792 ROM is preprogrammed with the following software and programs:

- Stellaris<sup>®</sup> Peripheral Driver Library

- Stellaris® Boot Loader
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error-detection functionality

### 1.1.3 External Peripheral Interface (see page 342)

The External Peripheral Interface (EPI) provides access to external devices using a parallel path. Unlike communications peripherals such as SSI, UART, and I<sup>2</sup>C, the EPI is designed to act like a bus to external peripherals and memory. The EPI has the following features:

- 16-bit dedicated parallel bus for external peripherals and memory
- Memory interface supports contiguous memory access independent of data bus width, thus enabling code execution directly from SDRAM, SRAM and Flash memory
- Blocking and non-blocking reads
- Processor from timing details through use of an internal write FIFO
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for read and write
  - Read channel request asserted by programmable levels on the internal non-blocking read FIFO (NBRFIFO)
  - Write channel request asserted by empty on the internal write FIFO (WFIFO)

The EPI supports three primary functional modes: Synchronous Dynamic Random Access Memory (SDRAM) mode, Traditional Host-Bus mode, and General-Purpose mode. The EPI module also provides custom GPIOs; however, unlike regular GPIOs, the EPI module uses a FIFO in the same way as a communication mechanism and is speed-controlled using clocking.

- Synchronous Dynamic Random Access Memory (SDRAM)
  - Supports x16 (single data rate) SDRAM at up to 50 MHz
  - Supports low-cost SDRAMs up to 64 MB (512 Mb)
  - Includes automatic refresh and access to all banks/rows
  - Includes a Sleep/Standby mode to keep contents active with minimal power draw
  - Multiplexed address/data interface for reduced pin count
- Host-bus
  - Traditional x8 MCU bus interface capabilities
  - Similar device compatibility options as PIC, ATmega, 8051, and others
  - Access to SRAM, NOR Flash, and other devices, with up to 1 MB of addressing
  - Support of both muxed and de-muxed address and data

- Access to a range of devices supporting the non-address FIFO x8 interface variant, with support for external FIFO (XFIFO) `EMPTY` and `FULL` signals
- Speed controlled, with read and write data wait-state counters
- Manual chip-enable (or use extra address pins)
- General Purpose
  - Wide parallel interfaces for fast communications with CPLDs and FPGAs
  - Data widths up to 32-bits
  - Data rates up to 150 Mbytes/second
  - Optional “address” sizes from 4-bits to 16-bits
  - Optional clock output, read/write strobes, framing (with counter-based size), and clock-enable input
- General parallel GPIO
  - 1 to 32 bits, FIFOed with speed control
  - Useful for custom peripherals or for digital data acquisition and actuator controls

#### 1.1.4 Serial Communications Peripherals

The LM3S9792 controller supports both asynchronous and synchronous serial communications with:

- Ethernet MAC and PHY
- Two CAN 2.0 A/B Controllers
- USB 2.0 (full speed and low speed) OTG/Host/Device
- Three UARTs with IrDA and ISO 7816 support (one UART with full modem controls)
- Two I<sup>2</sup>C modules
- Two Synchronous Serial Interface Modules (SSI)
- Integrated Interchip Sound (I<sup>2</sup>S) Module

The following sections provide more detail on each of these communications functions.

##### 1.1.4.1 Ethernet Controller (see page 723)

Ethernet is a frame-based computer networking technology for local area networks (LANs). Ethernet has been standardized as IEEE 802.3. This specification defines a number of wiring and signaling standards for the physical layer, two means of network access at the Media Access Control (MAC)/Data Link Layer, and a common addressing format.

The Stellaris<sup>®</sup> Ethernet Controller consists of a fully integrated media access controller (MAC) and network physical (PHY) interface and has the following features:

- Conforms to the *IEEE 802.3-2002 specification*
  - 10BASE-T/100BASE-TX IEEE-802.3 compliant. Requires only a dual 1:1 isolation transformer interface to the line
  - 10BASE-T/100BASE-TX ENDEC, 100BASE-TX scrambler/descrambler
  - Full-featured auto-negotiation
- Multiple operational modes
  - Full- and half-duplex 100 Mbps
  - Full- and half-duplex 10 Mbps
  - Power-saving and power-down modes
- Highly configurable
  - Programmable MAC address
  - LED activity selection
  - Promiscuous mode support
  - CRC error-rejection control
  - User-configurable interrupts
- Physical media manipulation
  - MDI/MDI-X cross-over support through software assist
  - Register-programmable transmit amplitude
  - Automatic polarity correction and 10BASE-T signal reception
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive channel request asserted on packet receipt
  - Transmit channel request asserted on empty transmit FIFO

#### 1.1.4.2 Controller Area Network (see page 677)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or twisted-pair wire. Originally created for automotive purposes, it is now used in many embedded control applications (for example, industrial or medical). Bit rates up to 1Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit

from 0 to 8 bytes of user information. The LM3S9792 microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the `CANnTX` and `CANnRX` signals

#### 1.1.4.3 USB (see page 771)

Universal Serial Bus (USB) is a serial bus standard designed to allow peripherals to be connected and disconnected using a standardized interface without rebooting the system.

The LM3S9792 controller supports three configurations in USB 2.0 full and low speed: USB Device, USB Host, and USB On-The-Go (negotiated on-the-go as host or device when connected to other USB-enabled systems). The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation
- Integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory - one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive for up to 3 IN endpoints and 3 OUT endpoints
  - Burst requests
  - Channel requests asserted when FIFO contains required amount of data

#### 1.1.4.4 UART (see page 520)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The LM3S9792 controller includes three fully programmable 16C550-type UARTs. Although the functionality is similar to a 16C550 UART, this UART design is not register compatible. The UART can generate individually masked interrupts from the Rx, Tx, modem status, and error conditions. The module generates a single combined interrupt when any of the interrupts are asserted and are unmasked. The UARTs have the following features:

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- LIN protocol support
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- False-start bit detection
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Full modem handshake support (on UART1)
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)

- Separate channels for transmit and receive
- Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
- Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

#### 1.1.4.5 I<sup>2</sup>C (see page 610)

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL). The I<sup>2</sup>C bus interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

Each device on the I<sup>2</sup>C bus can be designated as either a master or a slave. Each I<sup>2</sup>C module supports both sending and receiving data as either a master or a slave and can operate simultaneously as both a master and a slave. Both the I<sup>2</sup>C master and slave can generate interrupts.

The LM3S9792 controller includes two I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both sending and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Two transmission speeds: Standard (100 Kbps) and Fast (400 Kbps)
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been sent or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

#### 1.1.4.6 SSI (see page 570)

Synchronous Serial Interface (SSI) is a four-wire bi-directional communications interface that converts data between parallel and serial. Each SSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral

device. Each SSI module can be configured as either a master or slave device. As a slave device, the SSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices. The TX and RX paths are buffered with separate internal FIFOs.

Each SSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the SSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

Each SSI module provide the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, 16 bits wide, 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when FIFO contains 4 entries

#### 1.1.4.7 Inter-Integrated Circuit Sound (I<sup>2</sup>S) Interface (see page 645)

The I<sup>2</sup>S interface is a configurable serial audio core that contains a transmit module and a receive module. The module is configurable for the I<sup>2</sup>S as well as Left-Justified and Right-Justified serial audio formats. Data can be in one of four modes: Stereo, Mono, Compact 16-bit Stereo and Compact 8-Bit Stereo.

The transmit and receive modules each have an 8-entry audio-sample FIFO. An audio sample can consist of a Left and Right Stereo sample, a Mono sample, or a Left and Right Compact Stereo sample. In Compact 16-Bit Stereo, each FIFO entry contains both the 16-bit left and 16-bit right samples, allowing efficient data transfers and requiring less memory space. In Compact 8-bit Stereo, each FIFO entry contains an 8-bit left and an 8-bit right sample, reducing memory requirements further.

Both the transmitter and receiver are capable of being a master or a slave.

The Stellaris<sup>®</sup> I<sup>2</sup>S interface has the following features:

- Configurable audio format supporting I<sup>2</sup>S, Left-justification, and Right-justification
- Configurable sample size from 8 to 32 bits

- Mono and Stereo support
- 8-, 16-, and 32-bit FIFO interface for packing memory
- Independent transmit and receive 8-entry FIFOs
- Configurable FIFO-level interrupt and  $\mu$ DMA requests
- Independent transmit and receive MCLK direction control
- Transmit and receive internal MCLK sources
- Independent transmit and receive control for serial clock and word select
- MCLK and SCLK can be independently set to master or slave
- Configurable transmit zero or last sample when FIFO empty
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Burst requests
  - Channel requests asserted when FIFO contains required amount of data

### 1.1.5 System Integration

The LM3S9792 controller provides a variety of standard system functions integrated into the device, including:

- Micro Direct Memory Access Controller ( $\mu$ DMA)
- System control and clocks including on-chip precision 16-MHz oscillator
- ARM Cortex SysTick Timer
- Four 32-bit timers (up to eight 16-bit)
- Eight Capture Compare PWM pins (CCP)
- Real-Time Clock
- Watchdog Timer
- 0-65 GPIOs, depending on configuration
  - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
  - Independently configurable to 2, 4 or 8 mA drive capability
  - Up to 4 GPIOs can have 18 mA drive capability

The following sections provide more detail on each of these functions.

### 1.1.5.1 Direct Memory Access (see page 226)

The LM3S9792 microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA ( $\mu$ DMA). The  $\mu$ DMA controller provides a way to offload data transfer tasks from the Cortex-M3 processor, allowing for more efficient use of the processor and the expanded available bus bandwidth. The  $\mu$ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The  $\mu$ DMA controller provides the following features:

- ARM PrimeCell® 32-channel configurable  $\mu$ DMA controller
- Support for multiple transfer modes
  - Memory-to-memory, memory-to-peripheral, peripheral-to-memory
  - Basic for simple transfer scenarios
  - Ping-pong for continuous data flow
  - Scatter-gather for a programmable list of arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules - USB, UART, Ethernet, GP Timer, ADC, EPI, SSI, I<sup>2</sup>S
  - Alternate channel assignments
  - One channel each for receive and transmit path for bidirectional modules
  - Dedicated channel for software-initiated transfers
  - Per-channel configurable bus arbitration scheme
  - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between  $\mu$ DMA controller and the processor core
  - $\mu$ DMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable device requests

- Interrupt on transfer completion, with a separate interrupt per channel

### 1.1.5.2 System Control and Clocks (see page 90)

System control determines the overall operation of the device. It provides information about the device, controls power-saving features, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

- Device identification information - version, part number, SRAM size, Flash size, and so on
- Power control
  - On-chip fixed Low Drop-Out (LDO) voltage regulator
  - Low-power options for microcontroller: Sleep and Deep-sleep modes with clock gating
  - Low-power options for on-chip modules: software controls shutdown of individual peripherals and memory
  - 3.3-V supply brown-out detection and reporting via interrupt or reset
- Multiple clock sources for microcontroller system clock
  - Precision Oscillator (PIOSC) - on-chip resource providing a 16 MHz  $\pm 1\%$  frequency at room temperature
    - 16 MHz  $\pm 3\%$  across temperature
    - Software power down control for low power modes
  - Main Oscillator (MOSC) - a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the `OSC0` input pin, or an external crystal is connected across the `OSC0` input and `OSC1` output pins.
    - External oscillator used with or without on-chip PLL - select supported frequencies from 1 MHz to 16.384 MHz.
    - External crystal - from DC to maximum device speed
  - Internal 30-kHz Oscillator - on chip resource providing a 30 kHz  $\pm 50\%$  frequency, used during power-saving modes
- Flexible reset sources
  - Power-on reset (POR)
  - Reset pin assertion
  - Brown-out reset (BOR) detector alerts to system power drops
  - Software reset
  - Watchdog timer reset
  - Internal low drop-out (LDO) regulator output goes unregulated

### 1.1.5.3 Four Programmable Timers (see page 388)

Programmable timers can be used to count or time external events that drive the Timer input pins. The Stellaris® General-Purpose Timer Module (GPTM) contains four GPTM blocks. Each GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions.

The Timer Module can be configured independently and has the following functional options:

- Count up or down
- 16- or 32-bit programmable one-shot timer
- 16- or 32-bit programmable periodic timer
- 16-bit general-purpose timer with an 8-bit prescaler
- 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- ADC event trigger
- User-enabled stalling when the controller asserts CPU Halt flag during debug (excluding RTC mode)
- 16-bit input-edge count- or time-capture modes
- 16-bit PWM mode with software-programmable output inversion of the PWM signal
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine.
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

### 1.1.5.4 CCP Pins (see page 393)

The LM3S9792 microcontroller includes eight Capture Compare PWM pins (CCP) which can be used by the General-Purpose Timer Module to time/count external events using the CCP pin as an input. Alternatively, the GPTM can generate a simple PWM output on the CCP pin. Each pin can be programmed to operate in the following modes:

- Capture - The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer captures and stores the current timer value when a programmed event occurs.
- Compare - The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer compares the current value with a stored value and generates an interrupt when a match occurs.
- PWM - The GP Timer is incremented/decremented by the system clock. A PWM signal is generated based on a match between the counter value and a value stored in a match register and is output on the CCP pin.

### 1.1.5.5 Watchdog Timers (see page 427)

A watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way. The Stellaris<sup>®</sup> Watchdog Timer can generate a nonmaskable interrupt (NMI) or a reset when a time-out value is reached. In addition, the Watchdog Timer is ARM FiRM-compliant and can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

The LM3S9792 microcontroller has two Watchdog Timer modules: Watchdog Timer 0 uses the system clock for its timer clock; Watchdog Timer 1 uses the PIOSC as its timer clock. The Stellaris<sup>®</sup> Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the controller asserts the CPU Halt flag during debug

### 1.1.5.6 Programmable GPIOs (see page 291)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections. The Stellaris<sup>®</sup> GPIO module is comprised of nine physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FiRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 0-65 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 960 for the signals available to each GPIO pin).

- 0-65 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant input/outputs
- Fast toggle capable of a change every two clock cycles
- Two means of port access: either Advanced Host Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code
- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines

- Can be used to initiate an ADC sample sequence
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can be configured with an 18-mA pad drive for high-current applications
  - Slew rate control for the 8-mA drive
  - Open drain enables
  - Digital input enables

## 1.1.6 Advanced Motion Control

The LM3S9792 controller provides motion control functions integrated into the device, including:

- Eight advanced PWM outputs for motion and energy applications
- Four fault inputs to promote low-latency shutdown
- Two Quadrature Encoder Inputs (QEI)

The following provides more detail on these motion control functions.

### 1.1.6.1 PWM (see page 883)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control. The LM3S9792 PWM module consists of four PWM generator blocks and a control block. Each PWM generator block contains one timer (16-bit down or up/down counter), two comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. Each PWM generator block produces two PWM signals that can either be independent signals or a single pair of complementary signals with dead-band delays inserted. PWM generator block has the following features:

- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match

- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified
- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended fault capabilities with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

#### 1.1.6.2 **Fault Pins ( (see page 889))**

The LM3S9792 PWM module includes four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled.

#### 1.1.6.3 **QEI (see page 942)**

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, the position, direction of rotation, and speed can be tracked. In addition, a third channel, or index signal, can be used to reset the position counter. The Stellaris<sup>®</sup> quadrature encoder with index (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel. The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system). The LM3S9792 microcontroller includes two QEI modules providing control of two motors at the same time. The QEI module has the following features:

- Position integrator that tracks the encoder position

- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

## 1.1.7 Analog

The LM3S9792 controller provides analog functions integrated into the device, including:

- Two 10-bit Analog-to-Digital Converters (ADC) with sixteen analog input channels and sample rate of one million samples/second
- Three analog comparators
- Digital Comparator
- On-chip voltage regulator

The following provides more detail on these analog functions.

### 1.1.7.1 ADC (see page 452)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. The Stellaris<sup>®</sup> ADC module features 10-bit conversion resolution and supports sixteen input channels plus an internal temperature sensor. Four buffered sample sequencers allow rapid sampling of up to eight analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. The LM3S9792 microcontroller provides two ADC modules. A digital comparator function is included which allows the conversion value to be diverted to a comparison unit that provides digital comparator. The ADC module has the following features:

- Sixteen analog input channels
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Sample rate of one million samples/second
- Flexible, configurable analog-to-digital conversion
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)

- Timers
- Analog Comparators
- PWM
- GPIO
- Hardware averaging of up to 64 samples for improved accuracy
- Digital comparison unit providing digital comparator
- Converter uses an internal 3-V reference or an external reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each sample sequencer
  - Burst request asserted when interrupt is triggered

#### 1.1.7.2 Analog Comparators (see page 871)

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result. The LM3S9792 microcontroller provides three independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge. Each comparator has the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of these voltages
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

#### 1.1.8 JTAG and ARM Serial Wire Debug (see page 78)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging. Luminary Micro replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module providing all the normal JTAG debug and test functionality plus

real-time access to system memory without halting the core or requiring any target resident code. See the *CoreSight™ Design Kit Technical Reference Manual* for details on SWJ-DP. The SWJ-DP interface has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
  - Data Watchpoint and Trigger (DWT) unit for implementing watchpoints, trigger resources, and system profiling
  - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
  - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

### 1.1.9 Packaging and Temperature

- Industrial-range 100-pin RoHS-compliant LQFP package

## 1.2 Target Applications

The Stellaris® family is positioned for cost-conscious applications requiring significant control processing and connectivity capabilities such as:

- Remote monitoring
- Electronic point-of-sale (POS) machines
- Test and measurement equipment
- Network appliances and switches
- Factory automation
- HVAC and building control
- Gaming equipment
- Motion control
- Medical instrumentation
- Fire and security
- Power and energy

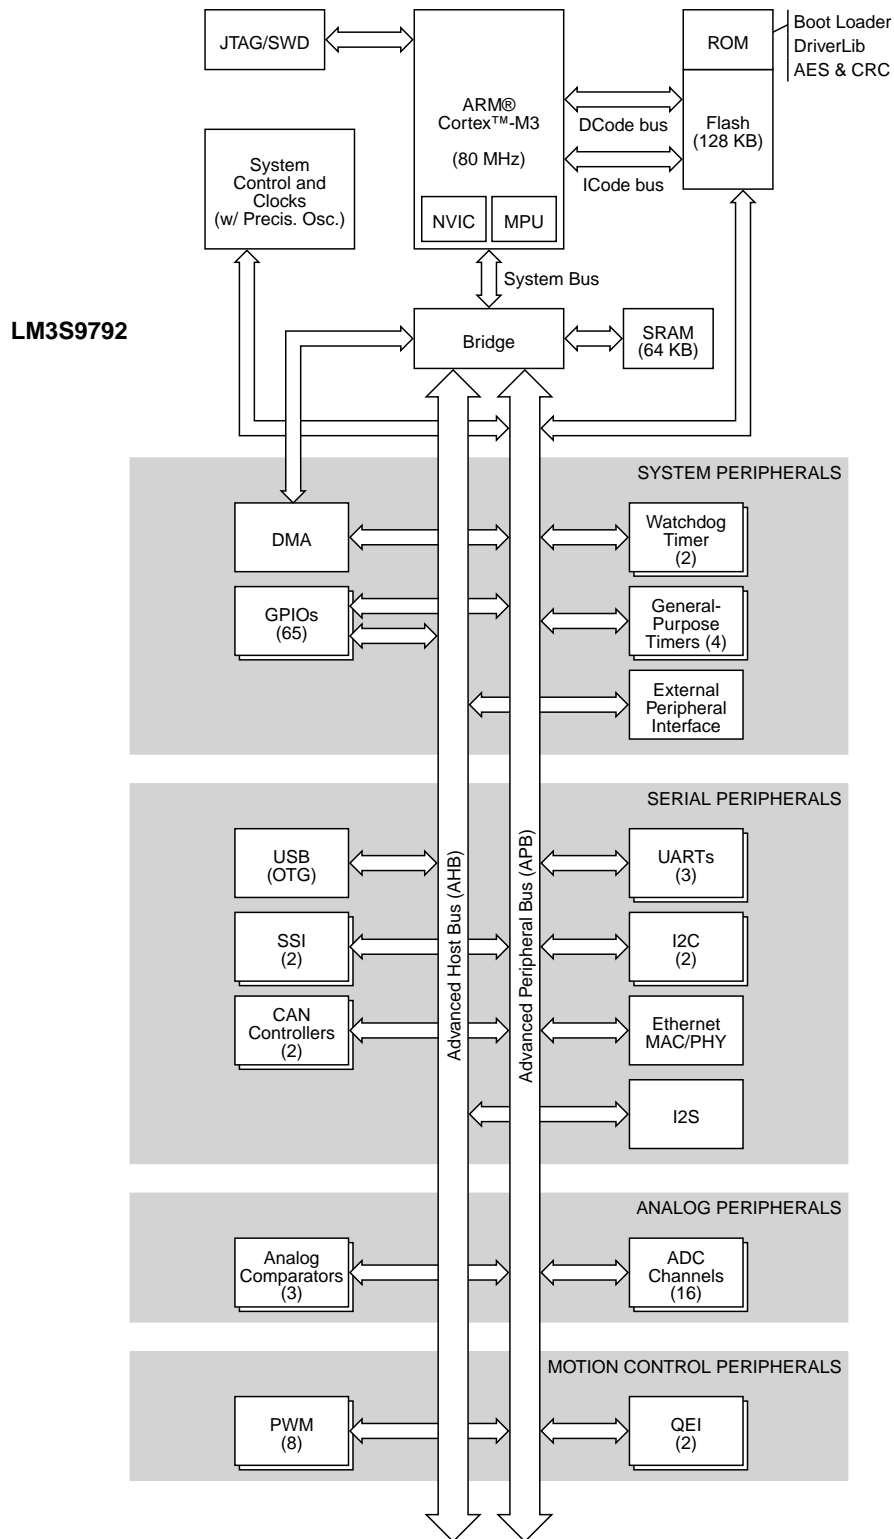

- Transportation

## 1.3 High-Level Block Diagram

Figure 1-1 depicts the features on the Stellaris<sup>®</sup> LM3S9792 microcontroller. Note that there are two on-chip buses that connect the core to the peripherals. The Advanced Peripheral Bus (APB) bus is the legacy bus. The Advanced Host Bus (AHB) bus provides better back-to-back access performance than the APB bus.

Figure 1-1. Stellaris<sup>®</sup> LM3S9792 Microcontroller High-Level Block Diagram

## 1.4 Additional Features

### 1.4.1 Memory Map (see page 72)

A memory map lists the location of instructions and data in memory. The memory map for the LM3S9792 controller can be found in “Memory Map” on page 72. Register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map. The *ARM® Cortex™-M3 Technical Reference Manual* provides further information on the memory map.

### 1.4.2 Hardware Details

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 959
- “Signal Tables” on page 960
- “Operating Characteristics” on page 992
- “Electrical Characteristics” on page 993
- “Package Information” on page 1020

## 2 ARM Cortex-M3 Processor Core

The ARM Cortex-M3 processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- 32-bit ARM® Cortex™-M3 v7M architecture optimized for small-footprint embedded applications
- Thumb-2 mixed 16-/32-bit instruction set, delivers the high performance expected of from a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices; typically in the range of a few kilobytes of memory for microcontroller-class applications
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- Harvard architecture characterized by separate buses for instruction and data
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash usage
- 80-MHz operation
- 1.25 DMIPS/MHz

The Stellaris® family of microcontrollers builds on this core to bring high-performance 32-bit computing to cost-sensitive embedded microcontroller applications, such as factory automation and control, industrial control power devices, building and home automation, and stepper motors.

For more information on the ARM Cortex-M3 processor core, see the *ARM® Cortex™-M3 Technical Reference Manual*. For information on SWJ-DP, see the *ARM® CoreSight Technical Reference Manual*.

## 2.1 Block Diagram

Figure 2-1. CPU Block Diagram

## 2.2 Functional Description

**Important:** The *ARM® Cortex™-M3 Technical Reference Manual* describes all the features of an ARM Cortex-M3 in detail. However, these features differ based on the implementation. This section describes the Stellaris® implementation.

Luminary Micro implements the ARM Cortex-M3 core as shown in Figure 2-1 on page 60. The Cortex-M3 uses the entire 16-bit Thumb instruction set and the base Thumb-2 32-bit instruction set. In addition, as noted in the *ARM® Cortex™-M3 Technical Reference Manual*, several Cortex-M3 components are flexible in their implementation: SW/JTAG-DP, ETM, TPIU, the ROM table, the MPU, and the Nested Vectored Interrupt Controller (NVIC). Each of these is addressed in the sections that follow.

### 2.2.1 Programming Model

This section provides a brief overview of the programming model for the Cortex-M3 core. More detailed information can be found in the *ARM® Cortex™-M3 Technical Reference Manual*.

- Privileged access and user access - Code can execute as privileged or unprivileged. Unprivileged execution limits or excludes access to some resources. Privileged execution has access to all resources. Handler mode is always privileged. Thread mode can be privileged or unprivileged. Thread mode is privileged out of reset, but you can change it to user or unprivileged by setting the CONTROL[0] bit using the MSR instruction. User access prevents:
  - Use of some instructions such as CPS to set FAULTMASK and PRIMASK

- Access to most registers in System Control Space (SCS)

When Thread mode has been changed from privileged to user, it cannot change itself back to privileged. Only a Handler can change the privilege of Thread mode. Handler mode is always privileged.

- Register set - The processor has the following 32-bit registers:
  - 13 general-purpose registers, r0-r12
  - Stack point alias of banked registers, SP\_process and SP\_main
  - Link register, r14
  - Program counter, r15
  - One program status register, xPSR.
- Data types - The processor supports the following data types:
  - 32-bit words
  - 16-bit halfwords
  - 8-bit bytes
- Memory formats - The processor views memory as a linear collection of bytes numbered in ascending order from 0. For example, bytes 0-3 hold the first stored word and bytes 4-7 hold the second stored word. The processor accesses code and data in little-endian format. In little-endian format, the byte with the lowest address in a word is the least-significant byte of the word. The byte with the highest address in a word is the most significant. The byte at address 0 of the memory system connects to data lines 7-0.
- Instruction set - The Cortex-M3 instruction set contains both 16 and 32-bit instructions. These instructions are summarized in Table 2-1 on page 61 and Table 2-2 on page 63, respectively.

**Table 2-1. 16-Bit Cortex-M3 Instruction Set Summary**

Operation	Assembler
Add register value and C flag to register value	ADC <Rd>, <Rm>
Add immediate 3-bit value to register	ADD <Rd>, <Rn>, #<immed_3>
Add immediate 8-bit value to register	ADD <Rd>, #<immed_8>
Add low register value to low register value	ADD <Rd>, <Rn>, <Rm>
Add high register value to low or high register value	ADD <Rd>, <Rm>
Add 4* (immediate 8-bit value) with PC to register	ADD <Rd>, PC, #<immed_8> * 4
Add 4* (immediate 8-bit value) with SP to register	ADD <Rd>, SP, #<immed_8> * 4
Add 4* (immediate 7-bit value) to SP	ADD SP, #<immed_7> * 4
Bitwise AND register values	AND <Rd>, <Rm>
Arithmetic shift right by immediate number	ASR <Rd>, <Rm>, #<immed_5>
Arithmetic shift right by number in register	ASR <Rd>, <Rs>
Branch conditional	B<cond> <target address>
Branch unconditional	B <target_address>
Bit clear	BIC <Rd>, <Rm>

Operation	Assembler
Software breakpoint	BKPT <immed_8>
Branch with link	BL <Rm>
Branch with link and exchange	BLX <Rm>
Branch and exchange	BX <Rm>
Compare not zero and branch	CBNZ <Rn>, <label>
Compare zero and branch	CBZ <Rn>, <label>
Compare negation of register value with another register value	CMN <Rn>, <Rm>
Compare immediate 8-bit value	CMP <Rn>, #<immed_8>
Compare registers	CMP <Rn>, <Rm>
Compare high register to low or high register	CMP <Rn>, <Rm>
Change processor state	CPS <effect>, <iflags>
Copy high or low register value to another high or low register	CPY <Rd> <Rm>
Bitwise exclusive OR register values	EOR <Rd>, <Rm>
Condition the following instruction	IT <cond>
Condition the following two instructions	IT<x> <cond>
Condition the following three instructions	IT<x><y> <cond>
Condition the following four instructions	IT<x><y><z> <cond>
Multiple sequential memory word loads	LDMIA <Rn>!, <registers>
Load memory word from base register address + 5-bit immediate offset	LDR <Rd>, [<Rn>, #<immed_5> * 4]
Load memory word from base register address + register offset	LDR <Rd>, [<Rn>, <Rm>]
Load memory word from PC address + 8-bit immediate offset	LDR <Rd>, [PC, #<immed_8> * 4]
Load memory word from SP address + 8-bit immediate offset	LDR, <Rd>, [SP, #<immed_8> * 4]
Load memory byte [7:0] from register address + 5-bit immediate offset	LDRB <Rd>, [<Rn>, #<immed_5>]
Load memory byte [7:0] from register address + register offset	LDRB <Rd>, [<Rn>, <Rm>]
Load memory halfword [15:0] from register address + 5-bit immediate offset	LDRH <Rd>, [<Rn>, #<immed_5> * 2]
Load halfword [15:0] from register address + register offset	LDRH <Rd>, [<Rn>, <Rm>]
Load signed byte [7:0] from register address + register offset	LDRSB <Rd>, [<Rn>, <Rm>]
Load signed halfword [15:0] from register address + register offset	LDRSH <Rd>, [<Rn>, <Rm>]
Logical shift left by immediate number	LSL <Rd>, <Rm>, #<immed_5>
Logical shift left by number in register	LSL <Rd>, <Rs>
Logical shift right by immediate number	LSR <Rd>, <Rm>, #<immed_5>
Logical shift right by number in register	LSR <Rd>, <Rs>
Move immediate 8-bit value to register	MOV <Rd>, #<immed_8>
Move low register value to low register	MOV <Rd>, <Rn>
Move high or low register value to high or low register	MOV <Rd>, <Rm>
Multiply register values	MUL <Rd>, <Rm>
Move complement of register value to register	MVN <Rd>, <Rm>
Negate register value and store in register	NEG <Rd>, <Rm>
No operation	NOP <c>
Bitwise logical OR register values	ORR <Rd>, <Rm>
Pop registers from stack	POP <registers>
Pop registers and PC from stack	POP <registers, PC>
Push registers onto stack	PUSH <registers>

Operation	Assembler
Push LR and registers onto stack	PUSH <registers, LR>
Reverse bytes in word and copy to register	REV <Rd>, <Rn>
Reverse bytes in two halfwords and copy to register	REV16 <Rd>, <Rn>
Reverse bytes in low halfword [15:0], sign-extend, and copy to register	REVSH <Rd>, <Rn>
Rotate right by amount in register	ROR <Rd>, <Rs>
Subtract register value and C flag from register value	SBC <Rd>, <Rm>
Send event	SEV <c>
Store multiple register words to sequential memory locations	STMIA <Rn>!, <registers>
Store register word to register address + 5-bit immediate offset	STR <Rd>, [<Rn>, #<immed_5> * 4]
Store register word to register address	STR <Rd>, [<Rn>, <Rm>]
Store register word to SP address + 8-bit immediate offset	STR <Rd>, [SP, #<immed_8> * 4]
Store register byte [7:0] to register address + 5-bit immediate offset	STRB <Rd>, [<Rn>, #<immed_5>]
Store register byte [7:0] to register address	STRB <Rd>, [<Rn>, <Rm>]
Store register halfword [15:0] to register address + 5-bit immediate offset	STRH <Rd>, [<Rn>, #<immed_5> * 2]
Store register halfword [15:0] to register address + register offset	STRH <Rd>, [<Rn>, <Rm>]
Subtract immediate 3-bit value from register	SUB <Rd>, <Rn>, #<immed_3>
Subtract immediate 8-bit value from register value	SUB <Rd>, #<immed_8>
Subtract register values	SUB <Rd>, <Rn>, <Rm>
Subtract 4 (immediate 7-bit value) from SP	SUB SP, #<immed_7> * 4
Operating system service call with 8-bit immediate call code	SVC <immed_8>
Extract byte [7:0] from register, move to register, and sign-extend to 32 bits	SXTB <Rd>, <Rm>
Extract halfword [15:0] from register, move to register, and sign-extend to 32 bits	SXTH <Rd>, <Rm>
Test register value for set bits by ANDing it with another register value	TST <Rn>, <Rm>
Extract byte [7:0] from register, move to register, and zero-extend to 32 bits	UXTB <Rd>, <Rm>10
Extract halfword [15:0] from register, move to register, and zero-extend to 32 bits	UXTH <Rd>, <Rm>
Wait for event	WFE <c>
Wait for interrupt	WFI <c>

Table 2-2. 32-Bit Cortex-M3 Instruction Set Summary

Operation	Assembler
Add register value, immediate 12-bit value, and C bit	ADC{S}.W <Rd>, <Rn>, #<modify_constant(immed_12)>
Add register value, shifted register value, and C bit	ADC{S}.W <Rd>, <Rn>, <Rm>{, <shift>}
Add register value and immediate 12-bit value	ADD{S}.W <Rd>, <Rn>, #<modify_constant(immed_12)>
Add register value and shifted register value	ADD{S}.W <Rd>, <Rm>{, <shift>}
Add register value and immediate 12-bit value	ADDW.W <Rd>, <Rn>, #<immed_12>
Bitwise AND register value with immediate 12-bit value	AND{S}.W <Rd>, <Rn>, #<modify_constant(immed_12)>
Bitwise AND register value with shifted register value	AND{S}.W <Rd>, <Rn>, <Rm>{, <shift>}
Arithmetic shift right by number in register	ASR{S}.W <Rd>, <Rn>, <Rm>
Conditional branch	B{cond}.W <label>
Clear bit field	BFC.W <Rd>, #<lsb>, #<width>
Insert bit field from one register value into another	BFI.W <Rd>, <Rn>, #<lsb>, #<width>

Operation	Assembler
Bitwise AND register value with complement of immediate 12-bit value	BIC{S}.W <Rd>, <Rn>, #<modify_constant(immed_12)>
Bitwise AND register value with complement of shifted register value	BIC{S}.W <Rd>, <Rn>, <Rm>{, <shift>}
Branch with link	BL <label>
Branch with link (immediate)	BL<c> <label>
Unconditional branch	B.W <label>
Clear exclusive clears the local record of the executing processor that an address has had a request for an exclusive access.	CLREX <c>
Return number of leading zeros in register value	CLZ.W <Rd>, <Rn>
Compare register value with two's complement of immediate 12-bit value	CMN.W <Rn>, #<modify_constant(immed_12)>
Compare register value with two's complement of shifted register value	CMN.W <Rn>, <Rm>{, <shift>}
Compare register value with immediate 12-bit value	CMP.W <Rn>, #<modify_constant(immed_12)>
Compare register value with shifted register value	CMP.W <Rn>, <Rm>{, <shift>}
Data memory barrier	DMB <c>
Data synchronization barrier	DSB <c>
Exclusive OR register value with immediate 12-bit value	EOR{S}.W <Rd>, <Rn>, #<modify_constant(immed_12)>
Exclusive OR register value with shifted register value	EOR{S}.W <Rd>, <Rn>, <Rm>{, <shift>}
Instruction synchronization barrier	ISB <c>
Load multiple memory registers, increment after or decrement before	LDM{IA DB}.W <Rn>{!}, <registers>
Memory word from base register address + immediate 12-bit offset	LDR.W <Rxf>, [<Rn>, #<offset_12>]
Memory word to PC from register address + immediate 12-bit offset	LDR.W PC, [<Rn>, #<offset_12>]
Memory word to PC from base register address immediate 8-bit offset, postindexed	LDR.W PC, [<Rn>], #<+/-<offset_8>
Memory word from base register address immediate 8-bit offset, postindexed	LDR.W <Rxf>, [<Rn>], #<+/-<offset_8>
Memory word from base register address immediate 8-bit offset, preindexed	LDR.W <Rxf>, [<Rn>, #<+/-<offset_8>!] LDRT.W <Rxf>, [<Rn>, #<offset_8>]
Memory word to PC from base register address immediate 8-bit offset, preindexed	LDR.W PC, [<Rn>, #<+/-<offset_8>!]
Memory word from register address shifted left by 0, 1, 2, or 3 places	LDR.W <Rxf>, [<Rn>, <Rm>{, LSL #<shift>}]
Memory word to PC from register address shifted left by 0, 1, 2, or 3 places	LDR.W PC, [<Rn>, <Rm>{, LSL #<shift>}]
Memory word from PC address immediate 12-bit offset	LDR.W <Rxf>, [PC, #<+/-<offset_12>]
Memory word to PC from PC address immediate 12-bit offset	LDR.W PC, [PC, #<+/-<offset_12>]
Memory byte [7:0] from base register address + immediate 12-bit offset	LDRB.W <Rxf>, [<Rn>, #<offset_12>]
Memory byte [7:0] from base register address immediate 8-bit offset, postindexed	LDRB.W <Rxf>, [<Rn>], #<+/-<offset_8>
Memory byte [7:0] from register address shifted left by 0, 1, 2, or 3 places	LDRB.W <Rxf>, [<Rn>, <Rm>{, LSL #<shift>}]
Memory byte [7:0] from base register address immediate 8-bit offset, preindexed	LDRB.W <Rxf>, [<Rn>, #<+/-<offset_8>!]
Memory byte from PC address immediate 12-bit offset	LDRB.W <Rxf>, [PC, #<+/-<offset_12>]
Memory doubleword from register address 8-bit offset 4, preindexed	LDRD.W <Rxf>, <Rxf2>, [<Rn>, #<+/-<offset_8> * 4]{!}

Operation	Assembler
Memory doubleword from register address 8-bit offset 4, postindexed	LDRD.W <Rxf>, <Rxf2>, [<Rn>], #+/-<offset_8> * 4
Load register exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register	LDREX<c> <Rt>,[<Rn>{,<#imm>}]
Load register exclusive halfword calculates an address from a base register value and an immediate offset, loads a halfword from memory, writes it to a register	LDREXH<c> <Rt>,[<Rn>{,<#imm>}]
Load register exclusive byte calculates an address from a base register value and an immediate offset, loads a byte from memory, writes it to a register	LDREXB<c> <Rt>,[<Rn>{,<#imm>}]

## 2.2.2 Serial Wire and JTAG Debug

Luminary Micro replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. As a result, Chapter 12, “Debug Port,” of the *ARM® Cortex™-M3 Technical Reference Manual* does not apply to Stellaris® devices.

The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *CoreSight™ Design Kit Technical Reference Manual* for details on SWJ-DP.

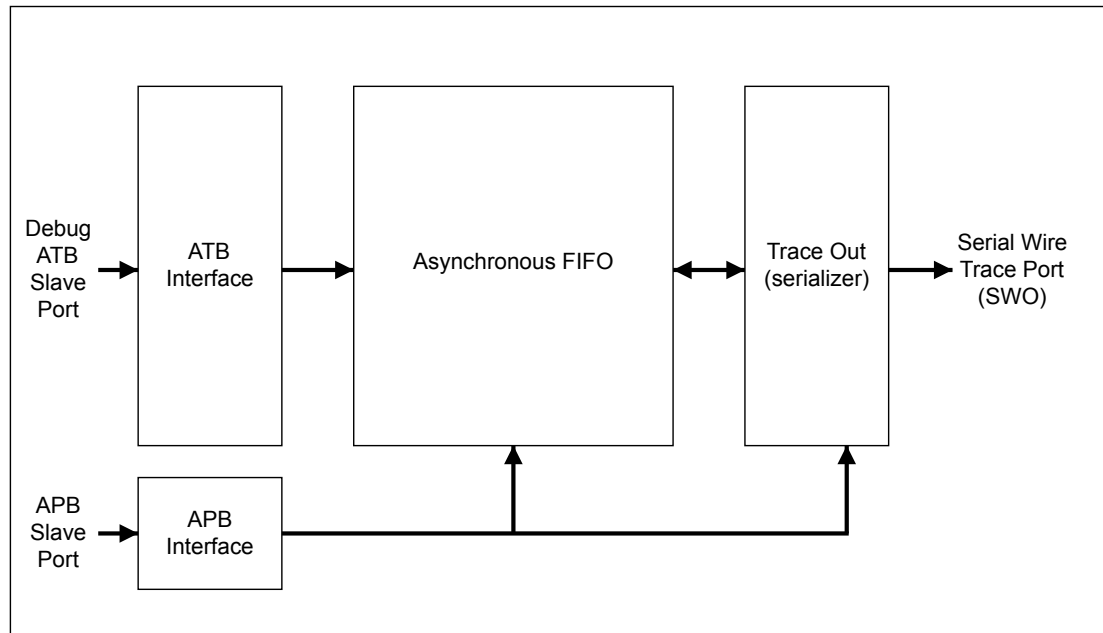

## 2.2.3 Embedded Trace Macrocell (ETM)

ETM is not implemented in the Stellaris® devices. As a result, Chapters 15 and 16 of the *ARM® Cortex™-M3 Technical Reference Manual* can be ignored.

## 2.2.4 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M3 trace data from the ITM, and an off-chip Trace Port Analyzer. Stellaris<sup>®</sup> devices implement the TPIU as shown in Figure 2-2. This implementation is similar to the non-ETM version described in the *ARM<sup>®</sup> Cortex<sup>™</sup>-M3 Technical Reference Manual*, however, SWJ-DP only provides the Serial Wire Viewer (SWV) output format for the TPIU.

**Figure 2-2. TPIU Block Diagram**

## 2.2.5 ROM Table

The default ROM table is implemented as described in the *ARM<sup>®</sup> Cortex<sup>™</sup>-M3 Technical Reference Manual*.

## 2.2.6 Memory Protection Unit (MPU)

The Memory Protection Unit (MPU) is included on the LM3S9792 controller and supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

## 2.2.7 Nested Vectored Interrupt Controller (NVIC)

The Nested Vectored Interrupt Controller (NVIC):

- Facilitates low-latency exception and interrupt handling
- Controls power management
- Implements system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts. The NVIC maintains knowledge of the stacked (nested) interrupts to enable tail-chaining of interrupts.

You can only fully access the NVIC from privileged mode, but you can pend interrupts in user-mode by enabling the Configuration Control Register (see the ARM® Cortex™-M3 Technical Reference Manual). Any other user-mode access causes a bus fault.

All NVIC registers are accessible using byte, halfword, and word unless otherwise stated.

### 2.2.7.1 Interrupts

The *ARM® Cortex™-M3 Technical Reference Manual* describes the maximum number of interrupts and interrupt priorities. The LM3S9792 microcontroller supports 53 interrupts with eight priority levels.

In addition to the peripheral interrupts, the system also provides for a non-maskable interrupt (NMI). The NMI is generally used in safety critical applications where the immediate execution of an interrupt handler is required. The NMI signal is available as an external signal so that it may be generated by external circuitry. The NMI is also used internally as part of the main oscillator verification circuitry. More information on the non-maskable interrupt is located in “Non-Maskable Interrupt” on page 93.

## 2.2.8 System Timer (SysTick)

Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer which fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used
- An internal clock source control based on missing/meeting durations. The COUNTFLAG bit-field in the control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

### 2.2.8.1 Functional Description

The timer consists of three registers:

- SysTick Control and Status Register - a control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status
- SysTick Reload Value Register - the reload value for the counter, used to provide the counter's wrap value
- SysTick Current Value Register - the current value of the counter

A fourth register, the SysTick Calibration Value Register, is not implemented in the Stellaris® devices.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the SysTick Reload Value register on the next clock edge, then decrements on subsequent clocks. Clearing the SysTick Reload Value register disables the counter on the next wrap. When the counter reaches zero, the COUNTFLAG status bit is set. The COUNTFLAG bit clears on reads.

Writing to the SysTick Current Value register clears the register and the COUNTFLAG status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

If the core is in debug state (halted), the counter does not decrement. The timer is clocked with respect to a reference clock, which can be either the core clock or an external clock source.

### 2.2.8.2 SysTick Control and Status Register

Use the SysTick Control and Status Register to enable the SysTick features. The reset is 0x0000.0000.

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	COUNTFLAG	R/W	0	Count Flag When set, this bit indicates that the timer has counted to 0 since the last time this register was read. This bit is cleared by a read of the register. If read by the debugger using the DAP, this bit is cleared only if the MasterType bit in the AHB-AP Control Register is clear. Otherwise, the COUNTFLAG bit is not changed by the debugger read.
15:3	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	CLKSOURCE	R/W	0	Clock Source  Value Description 0 External reference clock. (Not implemented for Stellaris® microcontrollers.) 1 Core clock  Because an external reference clock is not supported, this bit must be set in order for SysTick to operate.
1	TICKINT	R/W	0	Tick Interrupt When set, this bit causes an interrupt to be generated to the NVIC when SysTick counts to 0. When clear, interrupt generation is disabled. Software can use the COUNTFLAG to determine if the counter has ever reached 0.
0	ENABLE	R/W	0	Enable When set, this bit enables SysTick to operate in a multi-shot way. That is, the counter loads the Reload value and begins counting down. On reaching 0, the COUNTFLAG bit is set and an interrupt is generated if enabled by TICKINT. The counter then loads the Reload value again and begins counting. When this bit is clear, the counter is disabled.

### 2.2.8.3 SysTick Reload Value Register

The SysTick Reload Value Register specifies the start value to load into the SysTick Current Value Register when the counter reaches 0. The start value can be between 1 and 0x00FF.FFFF. A start value of 0 is possible but has no effect because the SysTick interrupt and COUNTFLAG are activated when counting from 1 to 0.

SysTick can be configured as a multi-shot timer, repeated over and over, firing every N+1 clock pulses, where N is any value from 1 to 0x00FF.FFFF. For example, if a tick interrupt is required every 100 clock pulses, 99 must be written into the RELOAD field.

When configuring SysTick as a single-shot timer, a new value is written on each tick interrupt, and the actual count down value must be written. For example, if a tick is next required after 400 clock pulses, 400 must be written into the RELOAD field.

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	RELOAD	R/W	-	Reload Value Value to load into the SysTick Current Value Register when the counter reaches 0.

#### 2.2.8.4 SysTick Current Value Register

The SysTick Current Value Register contains the current value of the counter.

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	CURRENT	W1C	-	Current Value This field contains the current value at the time the register is accessed. No read-modify-write protection is provided, so change with care. This register is write-clear. Writing to it with any value clears the register to 0. Clearing this register also clears the COUNTFLAG bit of the SysTick Control and Status Register.

#### 2.2.8.5 SysTick Calibration Value Register

The SysTick Calibration Value register is not implemented.

### 3 Memory Map

The memory map for the LM3S9792 controller is provided in Table 3-1.

In this manual, register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map. See also Chapter 4, "Memory Map" in the *ARM® Cortex™-M3 Technical Reference Manual*.

Note that within the memory map, all reserved space returns a bus fault when read or written.

## 4 Interrupts

The ARM Cortex-M3 processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 4-1 on page 75 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 53 interrupts (listed in Table 4-2 on page 76).

Priorities on the system handlers are set with the NVIC System Handler Priority registers. Interrupts are enabled through the NVIC Interrupt Set Enable register and prioritized with the NVIC Interrupt Priority registers. Priorities can be grouped by splitting priority levels into pre-emption priorities and subpriorities. All of the interrupt registers are described in Chapter 8, “Nested Vectored Interrupt Controller” in the *ARM® Cortex™-M3 Technical Reference Manual*.

Internally, the highest user-programmable priority (0) is treated as fourth priority, after a Reset, Non-Maskable Interrupt (NMI), and a Hard Fault, in that order. Note that 0 is the default priority for all the programmable priorities.

If you assign the same priority level to two or more interrupts, their hardware priority (the lower position number) determines the order in which the processor activates them. For example, if both GPIO Port A and GPIO Port B are priority level 1, then GPIO Port A has higher priority.

**Important:** It may take several processor cycles after a write to clear an interrupt source for the NVIC to see the interrupt source de-assert. Thus if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while the NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This situation can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer).

See Chapter 5, “Exceptions” and Chapter 8, “Nested Vectored Interrupt Controller” in the *ARM® Cortex™-M3 Technical Reference Manual* for more information on exceptions and interrupts.

**Table 4-1. Exception Types**

Exception Type	Vector Number	Priority <sup>a</sup>	Description
-	0	-	Stack top is loaded from the first entry of the vector table on reset.
Reset	1	-3 (highest)	This exception is invoked on power up and warm reset. On the first instruction, Reset drops to the lowest priority (and then is called the base level of activation). This exception is asynchronous.
Non-Maskable Interrupt (NMI)	2	-2	This exception is caused by the assertion of the NMI signal or by using the NVIC Interrupt Control State register and cannot be stopped or preempted by any exception but Reset. This exception is asynchronous.
Hard Fault	3	-1	This exception is caused by all classes of Fault, when the fault cannot activate due to priority or the configurable fault handler has been disabled. This exception is synchronous.
Memory Management	4	programmable	This exception is caused by an MPU mismatch, including access violation and no match. This exception is synchronous.

Exception Type	Vector Number	Priority <sup>a</sup>	Description
Bus Fault	5	programmable	This exception is caused by a pre-fetch fault, memory access fault, and other address/memory related faults. This exception is synchronous when precise and asynchronous when imprecise.  This fault can be enabled or disabled.
Usage Fault	6	programmable	This exception is caused by a usage fault, such as undefined instruction executed or illegal state transition attempt. This exception is synchronous.
-	7-10	-	Reserved.
SVCcall	11	programmable	This exception is caused by a system service call with an SVC instruction. This exception is synchronous.
Debug Monitor	12	programmable	This exception is caused by the debug monitor (when not halting). This exception is synchronous, but only active when enabled. This exception does not activate if it is a lower priority than the current activation.
-	13	-	Reserved.
PendSV	14	programmable	This exception is caused by a penable request for system service. This exception is asynchronous and only pended by software.
SysTick	15	programmable	This exception is caused by the SysTick timer reaching 0, when it is enabled to generate an interrupt. This exception is asynchronous.
Interrupts	16 and above	programmable	This exception is caused by interrupts asserted from outside the ARM Cortex-M3 core and fed through the NVIC (prioritized). These exceptions are all asynchronous. Table 4-2 on page 76 lists the interrupts on the LM3S9792 controller.

a. 0 is the default priority for all the programmable priorities.

**Table 4-2. Interrupts**

Vector Number	Interrupt Number (Bit in Interrupt Registers)	Description
0-15	-	Processor exceptions
16	0	GPIO Port A
17	1	GPIO Port B

## 5 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The Luminary Micro JTAG controller works with the ARM JTAG controller built into the Cortex-M3 core by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Luminary Micro JTAG instructions select the Luminary Micro TDO output. The multiplexer is controlled by the Luminary Micro JTAG controller, which has comprehensive programming for the ARM, Luminary Micro, and unimplemented JTAG instructions.

The Stellaris® JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, EXTEST and INTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
  - Serial Wire JTAG Debug Port (SWJ-DP)
  - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
  - Data Watchpoint and Trigger (DWT) unit for implementing watchpoints, trigger resources, and system profiling
  - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
  - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

See the *ARM® Cortex™-M3 Technical Reference Manual* for more information on the ARM JTAG controller.

## 5.1 Block Diagram

Figure 5-1. JTAG Module Block Diagram

## 5.2 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 5-1 on page 79. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the  $TCK$  and  $TMS$  inputs. The current state of the TAP controller depends on the sequence of values captured on  $TMS$  at the rising edge of  $TCK$ . The TAP controller determines when the serial shift chains capture new data, shift data from  $TDI$  towards  $TDO$ , and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like  $EXTEST$  and  $INTEST$ , operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the  $BYPASS$  instruction to ensure that the serial path between  $TDI$  and  $TDO$  is always connected (see Table 5-2 on page 85 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 1001 for JTAG timing diagrams.

**Note:** Of all the possible reset sources, only Power-On reset (POR) and the assertion of the  $\overline{RST}$  input have any effect on the JTAG module. The pin configurations are reset by both the

$\overline{\text{RST}}$  input and POR, whereas the internal JTAG logic is only reset with POR. See “Reset Sources” on page 90 for more information on reset.

## 5.2.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TDO. These pins and their associated state after a power-on reset or reset caused by the  $\overline{\text{RST}}$  input are given in Table 5-1. Detailed information on each pin follows. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 291 for information on how to reprogram the configuration of these pins.

**Table 5-1. JTAG Port Pins State after Power-On Reset or  $\overline{\text{RST}}$  assertion**

Pin Name	Data Direction	Internal Pull-Up	Internal Pull-Down	Drive Strength	Drive Value
TCK	Input	Enabled	Disabled	N/A	N/A
TMS	Input	Enabled	Disabled	N/A	N/A
TDI	Input	Enabled	Disabled	N/A	N/A
TDO	Output	Enabled	Disabled	2-mA driver	High-Z

### 5.2.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks and to ensure that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset, assuring that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source (see page 317 and page 319).

### 5.2.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state may be entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 5-2 on page 82.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost (see page 317).

### 5.2.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, may present this data to the proper shift register chain. Because the TDI pin is sampled

on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost (see page 317).

#### 5.2.1.4 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset, assuring that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states (see page 317 and page 319).

#### 5.2.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 5-2. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). In order to reset the JTAG module after the microcontroller has been powered on, the TMS input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

Figure 5-2. Test Access Port State Machine

### 5.2.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows this information to be shifted out on TDO during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TDO, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 85.

### 5.2.4 Operational Considerations

Certain operational parameters must be considered when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

### 5.2.4.1 GPIO Functionality

When the microcontroller is reset with either a POR or  $\overline{\text{RST}}$ , the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality ( $\text{DEN}[3:0]$  set in the **Port C GPIO Digital Enable (GPIODEN)** register), enabling the pull-up resistors ( $\text{PUE}[3:0]$  set in the **Port C GPIO Pull-Up Select (GPIOPUR)** register) and enabling the alternate hardware function ( $\text{AFSEL}[3:0]$  set in the **Port C GPIO Alternate Function Select (GPIOAFSEL)** register) on the JTAG/SWD pins. See page 321, page 317 and page 311.

It is possible for software to configure these pins as GPIOs after reset by clearing  $\text{AFSEL}[3:0]$  in the **Port C GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

---

**Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.**

---

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the NMI pin ( $\text{PB7}$ ) and the four JTAG/SWD pins ( $\text{PC}[3:0]$ ). Writes to protected bits of the **GPIOAFSEL** register, **GPIOPUR** register, **GPIO Pull-Down Select (GPIOPDR)** register (see page 319), and **GPIODEN** register are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 323) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 324) have been set.

### 5.2.4.2 Recovering a "Locked" Microcontroller

**Note:** Performing the sequence below restores the nonvolatile registers discussed in “Nonvolatile Register Programming” on page 199 to their factory default values. The mass erase of the Flash memory caused by the sequence below occurs prior to the nonvolatile registers being restored.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug sequence that can be used to recover the microcontroller. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the microcontroller in reset mass erases the Flash memory. The sequence to recover the microcontroller is:

1. Assert and hold the  $\overline{\text{RST}}$  signal.
2. Perform steps 1. and 2. of the JTAG-to-SWD switch sequence on the section called “JTAG-to-SWD Switching” on page 84.
3. Perform steps 1. and 2. of the SWD-to-JTAG switch sequence on the section called “SWD-to-JTAG Switching” on page 84.
4. Perform steps 1. and 2. of the JTAG-to-SWD switch sequence.
5. Perform steps 1. and 2. of the SWD-to-JTAG switch sequence.
6. Perform steps 1. and 2. of the JTAG-to-SWD switch sequence.
7. Perform steps 1. and 2. of the SWD-to-JTAG switch sequence.

8. Perform steps 1. and 2. of the JTAG-to-SWD switch sequence.
9. Perform steps 1. and 2. of the SWD-to-JTAG switch sequence.
10. Perform steps 1. and 2. of the JTAG-to-SWD switch sequence.
11. Perform steps 1. and 2. of the SWD-to-JTAG switch sequence.
12. Release the  $\overline{\text{RST}}$  signal.
13. Wait 400 ms.
14. Power-cycle the microcontroller.

### 5.2.4.3 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M3 core without having to perform, or have any knowledge of, JTAG cycles. This integration is accomplished with a SWD preamble that is issued before the SWD session begins.

The switching preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequence of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Cortex™-M3 Technical Reference Manual* and the *ARM® CoreSight Technical Reference Manual*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This instance is the only one where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

#### **JTAG-to-SWD Switching**

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send the switching preamble to the microcontroller. The 16-bit TMS command for switching to SWD mode is defined as b1110.0111.1001.1110, transmitted LSB first. This command can also be represented as 0xE79E when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit JTAG-to-SWD switch command, 0xE79E, on TMS.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in SWD mode, the SWD goes into the line reset state before sending the switch sequence.

#### **SWD-to-JTAG Switching**

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch command to the microcontroller. The 16-bit TMS

command for switching to JTAG mode is defined as b1110.0111.0011.1100, transmitted LSB first. This command can also be represented as 0xE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit SWD-to-JTAG switch command, 0xE73C, on TMS.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in JTAG mode, the JTAG goes into the Test Logic Reset state before sending the switch sequence.

## 5.3 Initialization and Configuration

After a Power-On-Reset or an external reset ( $\overline{\text{RST}}$ ), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. To return the pins to their JTAG functions, enable the four JTAG pins (PC[3:0]) for their alternate function using the **GPIOAFSEL** register. In addition to enabling the alternate functions, any other changes to the GPIO pad configurations on the four JTAG pins (PC[3:0]) should be returned to their default settings.

## 5.4 Register Descriptions

The registers in the JTAG TAP Controller or Shift Register chains are not memory mapped and are not accessible through the on-chip Advanced Peripheral Bus (APB). Instead, the registers within the JTAG controller are all accessed serially through the TAP Controller. These registers include the Instruction Register and the six Data Registers.

### 5.4.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain connected between the JTAG TDI and TDO pins with a parallel load register. When the TAP Controller is placed in the correct states, bits can be shifted into the IR. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the IR bits is shown in Table 5-2. A detailed explanation of each instruction, along with its associated Data Register, follows.

**Table 5-2. JTAG Instruction Register Commands**

IR[3:0]	Instruction	Description
0x0	EXTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.
0x1	INTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction into the controller.
0x2	SAMPLE / PRELOAD	Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in.
0x8	ABORT	Shifts data into the ARM Debug Port Abort Register.
0xA	DPACC	Shifts data into and out of the ARM DP Access Register.
0xB	APACC	Shifts data into and out of the ARM AC Access Register.
0xE	IDCODE	Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.
0xF	BYPASS	Connects TDI to TDO through a single Shift Register chain.

IR[3:0]	Instruction	Description
All Others	Reserved	Defaults to the BYPASS instruction to ensure that TDI is always connected to TDO.

#### 5.4.1.1 EXTEST Instruction

The EXTEST instruction is not associated with its own Data Register chain. Instead, the EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. With tests that drive known values out of the controller, this instruction can be used to verify connectivity. While the EXTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 5.4.1.2 INTEST Instruction

The INTEST instruction is not associated with its own Data Register chain. Instead, the INTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the INTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the inputs are used to drive the signals going into the core rather than the signals coming from the GPIO pads. With tests that drive known values into the controller, this instruction can be used for testing. It is important to note that although the RST input pin is on the Boundary Scan Data Register chain, it is only observable. While the INTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

#### 5.4.1.3 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TDO. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out on TDO while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST and INTEST instructions to drive data into or out of the controller. See “Boundary Scan Data Register” on page 88 for more information.

#### 5.4.1.4 ABORT Instruction

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. See the “ABORT Data Register” on page 89 for more information.

#### 5.4.1.5 DPACC Instruction

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. See “DPACC Data Register” on page 89 for more information.

#### 5.4.1.6 APACC Instruction

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. See “APACC Data Register” on page 88 for more information.

#### 5.4.1.7 IDCODE Instruction

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TDO. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure input and output data streams. IDCODE is the default instruction loaded into the JTAG Instruction Register when a Power-On-Reset (POR) is asserted, or the Test-Logic-Reset state is entered. See “IDCODE Data Register” on page 87 for more information.

#### 5.4.1.8 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. See “BYPASS Data Register” on page 88 for more information.

### 5.4.2 Data Registers

The JTAG module contains six Data Registers. These serial Data Register chains include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT and are discussed in the following sections.

#### 5.4.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 5-3. The standard requires that every JTAG-compliant microcontroller implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x412F.C230. This value indicates an ARM Cortex-M3, Version 1 processor and allows the debuggers to automatically configure themselves to work correctly with the Cortex-M3 during debug.

**Figure 5-3. IDCODE Register Format**

**5.4.2.2 BYPASS Data Register**

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 5-4. The standard requires that every JTAG-compliant microcontroller implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

**Figure 5-4. BYPASS Register Format**

**5.4.2.3 Boundary Scan Data Register**

The format of the Boundary Scan Data Register is shown in Figure 5-5. Each GPIO pin, starting with a GPIO pin next to the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as shown in the figure. For detailed information on the order of the input, output, and output enable bits for each of the GPIO ports and any other pins included on the Boundary Scan Data Chain, please refer to the Stellaris® Family Boundary Scan Description Language (BSDL) files, downloadable from [www.luminarymicro.com](http://www.luminarymicro.com).

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST and INTEST instructions. The EXTEST instruction forces data out of the controller, and the INTEST instruction forces data into the controller.

**Figure 5-5. Boundary Scan Register Format**

**5.4.2.4 APACC Data Register**

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

#### **5.4.2.5 DPACC Data Register**

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

#### **5.4.2.6 ABORT Data Register**

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

## 6 System Control

System control configures the overall operation of the device and provides information about the device. Configurable features include reset control, NMI operation, power control, clock control, and low-power modes.

### 6.1 Functional Description

The System Control module provides the following capabilities:

- Device identification, see “Device Identification” on page 90
- Local control, such as reset (see “Reset Control” on page 90), power (see “Power Control” on page 94) and clock control (see “Clock Control” on page 94)
- System control (Run, Sleep, and Deep-Sleep modes), see “System Control” on page 99

#### 6.1.1 Device Identification

Several read-only registers provide software with information on the microcontroller, such as version, part number, SRAM size, Flash size, and other features. See the **DID0** (page 102), **DID1** (page 131), **DC0-DC9** (page 133) and **NVMSTAT** (page 157) registers.

#### 6.1.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

##### 6.1.2.1 Reset Sources

The LM3S9792 microcontroller has six sources of reset:

1. External reset input pin ( $\overline{\text{RST}}$ ) assertion (see page 91).
2. Power-on reset (POR) (see page 91).
3. Internal brown-out (BOR) detector (see page 92).
4. Software-initiated reset (with the software reset registers) (see page 92).
5. A watchdog timer reset condition violation (see page 93).
6. MOSC failure (see page 93).

Table 6-1 provides a summary of results of the various reset operations.

**Table 6-1. Reset Sources**

Reset Source	Core Reset?	JTAG Reset?	On-Chip Peripherals Reset?
$\overline{\text{RST}}$	Yes	Pin Config Only	Yes
Power-On Reset	Yes	Yes	Yes
Brown-Out Reset	Yes	No	Yes
Software Reset	Yes <sup>a</sup>	No	Yes <sup>b</sup>
Watchdog Reset	Yes	No	Yes

Reset Source	Core Reset?	JTAG Reset?	On-Chip Peripherals Reset?
MOSC Failure Reset	Yes	No	Yes

- By using the SYSRESETREQ bit in the ARM Cortex-M3 Application Interrupt and Reset Control register
- Programmable on a module-by-module basis using the Software Reset Control Registers.

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an internal POR is the cause, in which case, all the bits in the **RESC** register are cleared except for the POR indicator. A bit in the **RESC** register can be cleared by writing a 0.

### 6.1.2.2 $\overline{\text{RST}}$ Pin Assertion

The external reset pin ( $\overline{\text{RST}}$ ) resets the microcontroller including the core and all the on-chip peripherals except the JTAG TAP controller (see “JTAG Interface” on page 78). The external reset sequence is as follows:

- The external reset pin ( $\overline{\text{RST}}$ ) is asserted for the duration specified by  $T_{\text{MIN}}$  and then de-asserted (see “Reset” on page 1002).
- A few clock cycles from  $\overline{\text{RST}}$  de-assertion to the start of the reset sequence is necessary for synchronization.
- The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The external reset timing is shown in Figure 27-6 on page 1002.

### 6.1.2.3 Power-On Reset (POR)

**Note:** The power-on reset also resets the JTAG controller. An external reset does not.

The Power-On Reset (POR) circuit monitors the power supply voltage ( $V_{\text{DD}}$ ). The POR circuit generates a reset signal to all of the internal logic including JTAG when the power supply ramp reaches a threshold value ( $V_{\text{TH}}$ ). If the application only uses the POR circuit, the  $\overline{\text{RST}}$  input must be connected to the power supply ( $V_{\text{DD}}$ ) through a pull-up resistor (1K to 10K  $\Omega$ ).

The microcontroller must be operating within the specified operating parameters when the on-chip power-on reset pulse is complete. The 3.3-V power supply to the microcontroller must reach 3.0 V within 10 msec of  $V_{\text{DD}}$  crossing 2.0 V to guarantee proper operation. For applications that require the use of an external reset signal to hold the microcontroller in reset longer than the internal POR, the  $\overline{\text{RST}}$  input may be used with the circuit as shown in Figure 6-1.

**Figure 6-1. External Circuitry to Extend Reset**

The  $R_1$  and  $C_1$  components define the power-on delay. The  $R_2$  resistor mitigates any leakage from the  $\overline{RST}$  input. The diode ( $D_1$ ) discharges  $C_1$  rapidly when the power supply is turned off.

The Power-On Reset sequence is as follows:

1. The microcontroller waits for both external reset ( $\overline{RST}$ ) and internal POR to go inactive.
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The internal POR is only active on the initial power-up of the microcontroller. The Power-On Reset timing is shown in Figure 27-7 on page 1003.

#### 6.1.2.4 Brown-Out Reset (BOR)

The microcontroller provides a brown-out detection circuit that triggers if the power supply ( $V_{DD}$ ) drops below a brown-out threshold voltage ( $V_{BTH}$ ). If a brown-out condition is detected, the system may generate an interrupt or a system reset. Brown-out resets are controlled with the **Power-On and Brown-Out Reset Control (PBORCTL)** register. The  $BORIOR$  bit in the **PBORCTL** register must be set for a brown-out condition to trigger a reset; if  $BORIOR$  is clear, an interrupt is generated. The default condition is to generate an interrupt, so BOR must be enabled. When a Brown-out condition occurs during a Flash PROGRAM or ERASE operation, a full system reset is always triggered without regard to the setting in the **PBORCTL** register.

The result of a brown-out reset is equivalent to that of an assertion of the external  $\overline{RST}$  input, and the reset is held active until the proper  $V_{DD}$  level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in Figure 27-8 on page 1003.

#### 6.1.2.5 Software Reset

Software can reset a specific peripheral or generate a reset to the entire microcontroller.

Peripherals can be individually reset by software via three registers that control reset signals to each on-chip peripheral (see the **SRCRn** registers, see page 188). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset. The encoding of the reset registers is consistent with the encoding of the clock gating control for peripherals and on-chip functions (see “System Control” on page 99).

The entire microcontroller including the core can be reset by software by setting the **SYSRESETREQ** bit in the Cortex-M3 Application Interrupt and Reset Control register. The software-initiated system reset sequence is as follows:

1. A software microcontroller reset is initiated by setting the **SYSRESETREQ** bit in the ARM Cortex-M3 Application Interrupt and Reset Control register.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 27-9 on page 1003.

### 6.1.2.6 Watchdog Timer Reset

The Watchdog Timer module's function is to prevent system hangs. The LM3S9792 microcontroller has two Watchdog Timer modules in case one watchdog clock source fails. One watchdog is run off the system clock and the other is run off the Precision Internal Oscillator (PIOSC). Each module operates in the same manner except that because the PIOSC watchdog timer module is in a different clock domain, register accesses must have a time delay between them. The watchdog timer can be configured to generate an interrupt to the microcontroller on its first time-out and to generate a reset on its second time-out.

After the watchdog's first time-out event, the 32-bit watchdog counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register and resumes counting down from that value. If the timer counts down to zero again before the first time-out interrupt is cleared, and the reset signal has been enabled, the watchdog timer asserts its reset signal to the microcontroller. The watchdog timer reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.
3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

For more information on the Watchdog Timer module, see "Watchdog Timer" on page 427.

The watchdog reset timing is shown in Figure 27-10 on page 1003.

### 6.1.3 Non-Maskable Interrupt

The microcontroller has two sources of non-maskable interrupt (NMI):

- The assertion of the `NMI` signal
- A main oscillator verification error

If both sources of NMI are enabled, software must check that the main oscillator verification is the cause of the interrupt in order to distinguish between the two sources.

#### 6.1.3.1 NMI Pin

The alternate function to GPIO port pin B7 is an NMI signal. The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in "General-Purpose Input/Outputs (GPIOs)" on page 291. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function just like the GPIO port pins associated with JTAG/SWD functionality, see page 324. The active sense of the NMI signal is High; asserting the enabled NMI signal above  $V_{IH}$  initiates the NMI interrupt sequence.

#### 6.1.3.2 Main Oscillator Verification Failure

The LM3S9792 microcontroller provides a main oscillator verification circuit that generates an error condition if the oscillator is running too fast or too slow. The main oscillator verification circuit can be programmed to generate a reset event, at which time a Power-on Reset is generated and control is transferred to the NMI handler. The NMI handler is used to address the main oscillator verification failure because the necessary code can be removed from the general reset handler, speeding up reset processing. The detection circuit is enabled by setting the `CVAL` bit in the **Main Oscillator**

**Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status (MOSCFAIL) bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in “Main Oscillator Verification Circuit” on page 98.

### 6.1.4 Power Control

The Stellaris<sup>®</sup> microcontroller provides an integrated LDO regulator that may be used to provide power to the majority of the microcontroller’s internal logic. For power reduction, a non-programmable LDO may be used to scale the microcontroller’s 3.3 V input voltage to 1.2V. The voltage output has a minimum voltage of 1.08 V and a maximum of 1.35 V. The LDO delivers up to 60 ma.

Figure 6-2 shows the power architecture.

**Note:** On the printed circuit board, use the LDO output as the source of VDDC input. In addition, the LDO requires decoupling capacitors. See “On-Chip Low Drop-Out (LDO) Regulator Characteristics” on page 994.

**Figure 6-2. Power Architecture**

### 6.1.5 Clock Control

System control determines the control of clocks in this part.

### 6.1.5.1 Fundamental Clock Sources

There are multiple clock sources for use in the microcontroller:

- **Precision Internal Oscillator (PIOSC).** The precision internal oscillator is an on-chip clock source. It does not require the use of any external components. The PIOSC provides a clock that is 16 MHz  $\pm$ 1% at room temperature and  $\pm$ 3% across temperature. Applications that do not depend on highly accurate clock sources may use this clock source to reduce system cost. The precision internal oscillator is the clock source the microcontroller uses during and following POR. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference.
- **Main Oscillator (MOSC).** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins. If the PLL is being used, the crystal value must be one of the supported frequencies between 3.579545 MHz through 16.384 MHz (inclusive). If the PLL is not being used, the crystal may be any one of the supported frequencies between 1 MHz and 16.384 MHz. The single-ended clock source range is from DC through the specified speed of the microcontroller. The supported crystals are listed in the XTAL bit field in the RCC register (see page 113).
- **Internal 30-kHz Oscillator.** The internal 30-kHz oscillator is similar to the internal oscillator, except that it provides an operational frequency of 30 kHz  $\pm$  50%. It is intended for use during Deep-Sleep power-saving modes. This power-savings mode benefits from reduced internal switching and also allows the main oscillator to be powered down.

The internal system clock (SysClk), is derived from any of the above sources plus two others: the output of the main internal PLL and the precision internal oscillator divided by four (4 MHz  $\pm$  1%). The frequency of the PLL clock reference must be in the range of 3.579545 MHz to 16.384 MHz (inclusive). Table 6-2 on page 95 shows how the various clock sources can be used in a system.

**Table 6-2. Clock Source Options**

Clock Source	Drive PLL?		Used as SysClk?	
	Yes	No	Yes	No
Precision Internal Oscillator	Yes	BYPASS = 0, OSCSRC = 0x1	Yes	BYPASS = 1, OSCSRC = 0x1
Internal Oscillator divide by 4 (4 MHz $\pm$ 1%)	No	BYPASS = 1	Yes	BYPASS = 1, OSCSRC = 0x2
Main Oscillator	Yes	BYPASS = 0, OSCSRC = 0x0	Yes	BYPASS = 1, OSCSRC = 0x0
Internal 30-kHz Oscillator	No	BYPASS = 1	Yes	BYPASS = 1, OSCSRC = 0x3

The **Run-Mode Clock Configuration (RCC)** and **Run-Mode Clock Configuration 2 (RCC2)** registers provide control for the system clock. The **RCC2** register is provided to extend fields that offer additional encodings over the **RCC** register. When used, the **RCC2** register field values are used by the logic over the corresponding field in the **RCC** register. In particular, **RCC2** provides for a larger assortment of clock configuration options.

Figure 6-3 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be individually enabled/disabled. The ADC clock signal is automatically divided down to 16 MHz for proper ADC operation. The PWM clock signal is a synchronous divide of the system clock to provide the PWM circuit with more range (set with **PWMDIV** in **RCC**).

Figure 6-3. Main Clock Tree

- a. Control provided by RCC register bit/field.  
 b. Control provided by RCC register bit/field or RCC2 register bit/field, if overridden with RCC2 register bit USERCC2.  
 c. Control provided by RCC2 register bit/field.  
 d. Also may be controlled by DSLPCLKCFG when in deep sleep mode.  
 e. The USEFRACT and FRACT bit fields can also be used to influence the system clock for clock frequencies greater than 50 MHz..

**Note:** The figure above shows all features available on all Stellaris® Tempest-class microcontrollers.

### 6.1.5.2 Crystal Configuration for the Main Oscillator (MOSC)

The main oscillator supports the use of a select number of crystals. If the main oscillator is used by the PLL as a reference clock, the supported range of crystals is 3.579545 to 16.384 MHz, otherwise, the range of supported crystals is 1 to 16.384 MHz.

The `XTAL` bit in the **RCC** register (see page 113) describes the available crystal choices and default programming values.

Software configures the **RCC** register `XTAL` field with the crystal number. If the PLL is used in the design, the `XTAL` field value is internally translated to the PLL settings. Table 27-11 on page 999 shows the actual PLL frequency and error for a given crystal choice.

### 6.1.5.3 Main PLL Frequency Configuration

The main PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the main PLL to drive the output.

If the main oscillator provides the clock reference to the main PLL, the translation provided by hardware and used to program the PLL is available for software in the **XTAL to PLL Translation (PLLCFG)** register (see page 118). The internal translation provides a translation within  $\pm 1\%$  of the targeted PLL VCO frequency.

The Crystal Value field (`XTAL`) in the **Run-Mode Clock Configuration (RCC)** register (see page 113) describes the available crystal choices and default programming of the **PLLCFG** register. Any time the `XTAL` field changes, the new settings are translated and the internal PLL settings are updated.

The microcontroller powers up with the PIOSC running. To configure the PIOSC to be the clock source for the main PLL, program the `OSCR2` field in the **Run-Mode Clock Configuration 2 (RCC2)** register to be 0x1. If another clock source is desired, the PIOSC can be powered down by setting the `IOSCDIS` bit in the **RCC** register.

The PIOSC generates a 16 MHz clock with a  $\pm 1\%$  accuracy at room temperatures. Across the extended temperature range, the accuracy is  $\pm 3\%$ . At the factory, the PIOSC is set to 16 MHz at room temperature, however, the frequency can be trimmed for other voltage or temperature conditions using software in one of two ways:

- Default calibration: clear the `UTEN` bit and set the `UPDATE` bit in the **Precision Internal Oscillator Calibration (PIOSCCAL)** register.
- User-defined calibration: The user can program the `UT` value to adjust the PIOSC frequency. As the `UT` value increases, the generated period increases. To commit a new `UT` value, first set the `UTEN` bit, then program the `UT` field, and then set the `UPDATE` bit. The adjustment finishes within a few clock periods and is glitch free.

### 6.1.5.4 USB PLL Frequency Configuration

The USB PLL is disabled by default during power-on reset and is enabled later by software. The USB PLL must be enabled and running for proper USB function. The main oscillator is the only clock reference for the USB PLL. The USB PLL is enabled by clearing the `USBPWRDN` bit of the **RCC2** register. The `XTAL` bit field (Crystal Value) of the **RCC** register describes the available crystal choices. The main oscillator must be connected to one of the following crystal values in order to correctly generate the USB clock: 4, 5, 6, 8, 10, 12, or 16 MHz. Only these crystals provide the necessary USB PLL VCO frequency to conform with the USB timing specifications.

### 6.1.5.5 PLL Modes

Both PLLs have two modes of operation: Normal and Power-Down

- Normal: The PLL multiplies the input clock reference and drives the output.
- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the **RCC/RCC2** register fields (see page 113 and page 121).

#### 6.1.5.6 PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is  $T_{\text{READY}}$  (see Table 27-10 on page 999). During the relock time, the affected PLL is not usable as a clock reference.

Either PLL is changed by one of the following:

- Change to the  $XTAL$  value in the **RCC** register—writes of the same value do not cause a relock.
- Change in the PLL from Power-Down to Normal mode.

A counter is defined to measure the  $T_{\text{READY}}$  requirement. The counter is clocked by the main oscillator. The range of the main oscillator has been taken into account and the down counter is set to 0x1200 (that is, ~600  $\mu\text{s}$  at an 8.192 MHz external oscillator clock). When the  $XTAL$  value is greater than 0x0F, the down counter is set to 0x2400 to maintain the required lock time on higher frequency crystal inputs. Hardware is provided to keep the PLL from being used as a system clock until the  $T_{\text{READY}}$  condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RCC/RCC2** register is switched to use the PLL.

If the main PLL is enabled and the system clock is switched to use the PLL in one step, the system control hardware continues to clock the microcontroller from the oscillator selected by the **RCC/RCC2** register until the main PLL is stable ( $T_{\text{READY}}$  time met), after which it changes to the PLL. Software can use many methods to ensure that the system is clocked from the main PLL, including periodically polling the  $PLLLRIS$  bit in the **Raw Interrupt Status (RIS)** register, and enabling the PLL Lock interrupt.

The USB PLL is not protected during the lock time ( $T_{\text{READY}}$ ), and software should ensure that the USB PLL has locked before using the interface. Software can use many methods to ensure the  $T_{\text{READY}}$  period has passed, including periodically polling the  $USBPLLLRIS$  bit in the **Raw Interrupt Status (RIS)** register, and enabling the USB PLL Lock interrupt.

#### 6.1.5.7 Main Oscillator Verification Circuit

The clock control includes circuitry to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the  $CVAL$  bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, the following sequence is performed by the hardware:

1. The  $MOSCFAIL$  bit in the **Reset Cause (RESC)** register is set.
2. If the internal oscillator (PIOSC) is disabled, it is enabled.
3. The system clock is switched from the main oscillator to the PIOSC.
4. An internal power-on reset is initiated that lasts for 32 PIOSC periods.
5. Reset is de-asserted and the processor is directed to the NMI handler during the reset sequence.

## 6.1.6 System Control

For power-savings purposes, the **RCGCn**, **SCGCn**, and **DCGCn** registers control the clock gating logic for each peripheral or block in the system while the microcontroller is in Run, Sleep, and Deep-Sleep mode, respectively. The **DC1**, **DC2** and **DC4** registers act as a write mask for the **RCGCn**, **SCGCn**, and **DCGCn** registers.

There are three levels of operation for the microcontroller defined as:

- **Run Mode.** In Run mode, the microcontroller actively executes code. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the **RCGCn** registers. The system clock can be any of the available clock sources including the PLL.
- **Sleep Mode.** In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor and the memory subsystem are not clocked and therefore no longer execute code. Sleep mode is entered by the Cortex-M3 core executing a WFI (Wait for Interrupt) instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See the system control NVIC section of the *ARM® Cortex™-M3 Technical Reference Manual* for more details.

Peripherals are clocked that are enabled in the **SCGCn** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCn** register when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

- **Deep-Sleep Mode.** In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Run mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the microcontroller to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Deep-Sleep mode is entered by first writing the Deep Sleep Enable bit in the ARM Cortex-M3 NVIC system control register and then executing a WFI instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See the system control NVIC section of the *ARM® Cortex™-M3 Technical Reference Manual* for more details.

The Cortex-M3 processor core and the memory subsystem are not clocked. Peripherals are clocked that are enabled in the **DCGCn** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCn** register when auto-clock gating is disabled. The system clock source is the main oscillator by default or the internal oscillator specified in the **DSLPCCLKCFG** register if one is enabled. When the **DSLPCCLKCFG** register is used, the internal oscillator is powered up, if necessary, and the main oscillator is powered down. If the PLL is running at the time of the WFI instruction, hardware powers the PLL down and overrides the **SYSDIV** field of the active **RCC/RCC2** register, to be determined by the **DSDIVORIDE** setting in the **DSLPCCLKCFG** register, up to /16 or /64 respectively. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration. If the PIOSC is used as the PLL reference clock source, it may continue to provide the clock during Deep-Sleep. See page 125.

## 6.2 Initialization and Configuration

The PLL is configured using direct register writes to the **RCC/RCC2** register. If the **RCC2** register is being used, the **USERCC2** bit must be set and the appropriate **RCC2** bit/field is used. The steps required to successfully change the PLL-based system clock are:

1. Bypass the PLL and system clock divider by setting the **BYPASS** bit and clearing the **USESYS** bit in the **RCC** register, thereby configuring the microcontroller to run off a “raw” clock source

and allowing for the new PLL configuration to be validated before switching the system clock to the PLL.

2. Select the crystal value (*XTAL*) and oscillator source (*OSCSRC*), and clear the *PWRDN* bit in **RCC/RCC2**. Setting the *XTAL* field automatically pulls valid PLL configuration data for the appropriate crystal, and clearing the *PWRDN* bit powers and enables the PLL and its output.
3. Select the desired system divider (*SYSDIV*) in **RCC/RCC2** and set the *USESYS* bit in **RCC**. The *SYSDIV* field determines the system frequency for the microcontroller.
4. Wait for the PLL to lock by polling the *PLLLRIS* bit in the **Raw Interrupt Status (RIS)** register.
5. Enable use of the PLL by clearing the *BYPASS* bit in **RCC/RCC2**.

## 6.3 Register Map

Table 6-3 on page 100 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

**Note:** Spaces in the System Control register space that are not used are reserved for future or internal use by Luminary Micro, Inc. Software should not modify any reserved memory address.

Additional Flash and ROM registers defined in the System Control register space are described in the "Internal Memory" on page 195.

## 6.4 Register Descriptions

All addresses given are relative to the System Control base address of 0x400F.E000.

## Register 1: Device Identification 0 (DID0), offset 0x000

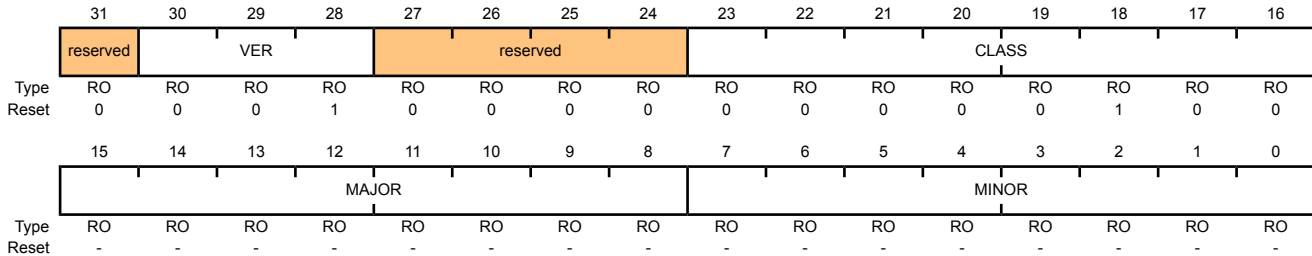

This register identifies the version of the microcontroller.

### Device Identification 0 (DID0)

Base 0x400F.E000

Offset 0x000

Type RO, reset -

Bit/Field	Name	Type	Reset	Description				
31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
30:28	VER	RO	0x1	<p>DID0 Version</p> <p>This field defines the <b>DID0</b> register format version. The version number is numeric. The value of the <code>VER</code> field is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Second version of the <b>DID0</b> register format.</td> </tr> </tbody> </table>	Value	Description	0x1	Second version of the <b>DID0</b> register format.
Value	Description							
0x1	Second version of the <b>DID0</b> register format.							
27:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
23:16	CLASS	RO	0x04	<p>Device Class</p> <p>The <code>CLASS</code> field value identifies the internal design from which all mask sets are generated for all microcontrollers in a particular product line. The <code>CLASS</code> field value is changed for new product lines, for changes in fab process (for example, a remap or shrink), or any case where the <code>MAJOR</code> or <code>MINOR</code> fields require differentiation from prior microcontrollers. The value of the <code>CLASS</code> field is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x04</td> <td>Stellaris® Tempest-class microcontrollers</td> </tr> </tbody> </table>	Value	Description	0x04	Stellaris® Tempest-class microcontrollers
Value	Description							
0x04	Stellaris® Tempest-class microcontrollers							

Bit/Field	Name	Type	Reset	Description								
15:8	MAJOR	RO	-	<p>Major Revision</p> <p>This field specifies the major revision number of the microcontroller. The major revision reflects changes to base layers of the design. The major revision number is indicated in the part number as a letter (A for first revision, B for second, and so on). This field is encoded as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>Revision A (initial device)</td></tr><tr><td>0x1</td><td>Revision B (first base layer revision)</td></tr><tr><td>0x2</td><td>Revision C (second base layer revision)</td></tr></tbody></table> <p>and so on.</p>	Value	Description	0x0	Revision A (initial device)	0x1	Revision B (first base layer revision)	0x2	Revision C (second base layer revision)
Value	Description											
0x0	Revision A (initial device)											
0x1	Revision B (first base layer revision)											
0x2	Revision C (second base layer revision)											
7:0	MINOR	RO	-	<p>Minor Revision</p> <p>This field specifies the minor revision number of the microcontroller. The minor revision reflects changes to the metal layers of the design. The MINOR field value is reset when the MAJOR field is changed. This field is numeric and is encoded as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>Initial device, or a major revision update.</td></tr><tr><td>0x1</td><td>First metal layer change.</td></tr><tr><td>0x2</td><td>Second metal layer change.</td></tr></tbody></table> <p>and so on.</p>	Value	Description	0x0	Initial device, or a major revision update.	0x1	First metal layer change.	0x2	Second metal layer change.
Value	Description											
0x0	Initial device, or a major revision update.											
0x1	First metal layer change.											
0x2	Second metal layer change.											

## Register 2: Brown-Out Reset Control (PBORCTL), offset 0x030

This register is responsible for controlling reset conditions after initial power-on reset.

### Brown-Out Reset Control (PBORCTL)

Base 0x400F.E000

Offset 0x030

Type R/W, reset 0x0000.7FFD

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved															BORIOR	reserved
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORIOR	R/W	0	BOR Interrupt or Reset
				Value Description
			0	A Brown Out Event causes an interrupt to be generated to the interrupt controller.
			1	A Brown Out Event causes a reset of the microcontroller.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

### Register 3: Raw Interrupt Status (RIS), offset 0x050

This register indicates the status for system control raw interrupts. An interrupt is sent to the interrupt controller if the corresponding bit in the **Interrupt Mask Control (IMC)** register is set. Writing a 1 to the corresponding bit in the **Masked Interrupt Status and Clear (MISC)** register clears an interrupt status bit.

#### Raw Interrupt Status (RIS)

Base 0x400F.E000

Offset 0x050

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPRIS	RO	0	MOSC Power Up Raw Interrupt Status  Value Description 1 Sufficient time has passed for the MOSC to reach the expected frequency. The value for this power-up time is indicated by $T_{MOSC\_SETTLE}$ . 0 Sufficient time has not passed for the MOSC to reach the expected frequency.  This bit is cleared by writing a 1 to the MOSCPUPMIS bit in the <b>MISC</b> register.
7	USBPLLRRIS	RO	0	USB PLL Lock Raw Interrupt Status  Value Description 1 The USB PLL timer has reached $T_{READY}$ indicating that sufficient time has passed for the USB PLL to lock. 0 The USB PLL timer has not reached $T_{READY}$ .  This bit is cleared by writing a 1 to the USBPLLRRMIS bit in the <b>MISC</b> register.
6	PLLLRRIS	RO	0	PLL Lock Raw Interrupt Status  Value Description 1 The PLL timer has reached $T_{READY}$ indicating that sufficient time has passed for the PLL to lock. 0 The PLL timer has not reached $T_{READY}$ .  This bit is cleared by writing a 1 to the PLLRRMIS bit in the <b>MISC</b> register.

Bit/Field	Name	Type	Reset	Description
5:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORRIS	RO	0	<p>Brown-Out Reset Raw Interrupt Status</p> <p>Value Description</p> <p>1 A brown-out condition is currently active.</p> <p>0 A brown-out condition is not currently active.</p> <p>Note the BORIOR bit in the <b>PBORCTL</b> register must be cleared to cause an interrupt due to a Brown Out Event.</p> <p>This bit is cleared by writing a 1 to the BORMIS bit in the <b>MISC</b> register.</p>
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 4: Interrupt Mask Control (IMC), offset 0x054

This register contains the mask bits for system control raw interrupts. A raw interrupt, indicated by a bit being set in the **Raw Interrupt Status (RIS)** register, is sent to the interrupt controller if the corresponding bit in this register is set.

### Interrupt Mask Control (IMC)

Base 0x400F.E000  
Offset 0x054

0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				

## Register 5: Masked Interrupt Status and Clear (MISC), offset 0x058

On a read, this register gives the current masked status value of the corresponding interrupt in the **Raw Interrupt Status (RIS)** register. All of the bits are R/W1C, thus writing a 1 to a bit clears the corresponding raw interrupt bit in the **RIS** register (see page 105).

### Masked Interrupt Status and Clear (MISC)

Base 0x400F.E000  
Offset 0x058

### Register 8: XTAL to PLL Translation (PLLCFG), offset 0x064

This register provides a means of translating external crystal frequencies into the appropriate PLL settings. This register is initialized during the reset sequence and updated anytime that the XTAL field changes in the Run-Mode Clock Configuration (RCC) register (see page 113).

The PLL frequency is calculated using the PLLCFG field values, as follows:

$$PLLFreq = OSCFreq * F / (R + 1)$$

#### XTAL to PLL Translation (PLLCFG)

Base 0x400F.E000

Offset 0x064

Type RO, reset -

Bit/Field	Name	Type	Reset	Description
31:14	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13:5	F	RO	-	PLL F Value This field specifies the value supplied to the PLL's F input.
4:0	R	RO	-	PLL R Value This field specifies the value supplied to the PLL's R input.

## Register 9: GPIO Host-Bus Control (GPIOHBCTL), offset 0x06C

This register controls which internal bus is used to access each GPIO port. When a bit is clear, the corresponding GPIO port is accessed across the legacy Advanced Peripheral Bus (APB) bus and through the APB memory aperture. When a bit is set, the corresponding port is accessed across the Advanced Host Bus (AHB) bus and through the AHB memory aperture. Each GPIO port can be individually configured to use AHB or APB, but may be accessed only through one aperture. The AHB bus provides better back-to-back access performance than the APB bus. The address aperture in the memory map changes for the ports that are enabled for AHB access (see Table 9-5 on page 299).

### Register 10: Run-Mode Clock Configuration 2 (RCC2), offset 0x070

This register overrides the **RCC** equivalent register fields when the **USERCC2** bit is set, allowing the extended capabilities of the **RCC2** register to be used while also providing a means to be backward-compatible to previous parts. The fields within the **RCC2** register occupy the same bit positions as they do within the **RCC** register as LSB-justified.

The **SYSDIV2** field is 2 bits wider than the **SYSDIV** field in the **RCC** register so that additional larger divisors are possible, allowing a lower system clock frequency for improved Deep Sleep power consumption. An additional bit, **FRACT**, has been added as an available LSB for **SYSDIV2** to provide additional frequency choices. **FRACT** can be modified when **USEFRACT** is set. The following table provides some examples of frequency choices using the **SYSDIV2**, **USEFRACT** and **FRACT** bits. The PLL VCO frequency is 400 MHz.

**Table 6-4. Examples of Possible System Clock Frequencies**

System Clock	SYSDIV2	USEFRACT	FRACT
20 MHz	0x09	0	don't care
20 MHz	0x09	1	1
25 MHz	0x07	0	don't care
40 MHz	0x04	0	don't care
44.4 MHz	0x04	1	0
50 MHz	0x03	0	don't care
80 MHz	0x02	1	0

### Register 11: Main Oscillator Control (MOSCCTL), offset 0x07C

This register provides the ability to enable the MOSC clock verification circuit. When enabled, this circuit monitors the frequency of the MOSC to verify that the oscillator is operating within specified limits. If the clock goes invalid after being enabled, the microcontroller issues a power-on reset and reboots to the NMI handler.

#### Main Oscillator Control (MOSCCTL)

Base 0x400F.E000

### Register 13: Deep Sleep Flash Configuration (DSFLASHCFG), offset 0x14C

This register allows the user to force the shutdown of the Flash subsystem during all Deep-Sleep periods. For deep-sleep periods that do not require a MOSC startup time or a PLL lock time, the microcontroller has a lockout period of 30-120  $\mu$ s for the Flash to start up after the event to exit deep sleep has occurred.

#### Deep Sleep Flash Configuration (DSFLASHCFG)

30:9	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	UPDATE	R/W	0	Update Trim  Value Description 1 Updates the PIOSC trim value with the UT bit or the DT bit in the <b>PIOSCSTAT</b> register. Used with UTEN. 0 No action.  This bit is auto-cleared after the update.
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	UT	R/W	0x0	User Trim Value  User trim value that can be loaded into the PIOSC.  Refer to “Main PLL Frequency Configuration” on page 97 for more information on calibrating the PIOSC.

## Register 15: I<sup>2</sup>S MCLK Configuration (I2SMCLKCFG), offset 0x170

This register configures the receive and transmit fractional clock dividers for the for the I<sup>2</sup>S master transmit and receive clocks (I2S0TXMCLK and I2S0RXMCLK) . Varying the integer and fractional inputs for the clocks allows greater accuracy in hitting the target I<sup>2</sup>S clock frequencies. Refer to “Clock Control” on page 649 for combinations of the TXI and TXF bits and the RXI and RXF bits that provide MCLK frequencies within acceptable error limits.

24	COMP0	RO	1	Analog Comparator 0 Present When set, indicates that analog comparator 0 is present.
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	RO	1	Timer Module 3 Present When set, indicates that General-Purpose Timer module 3 is present.

Bit/Field	Name	Type	Reset	Description
18	TIMER2	RO	1	Timer Module 2 Present When set, indicates that General-Purpose Timer module 2 is present.
17	TIMER1	RO	1	Timer Module 1 Present When set, indicates that General-Purpose Timer module 1 is present.
16	TIMER0	RO	1	Timer Module 0 Present When set, indicates that General-Purpose Timer module 0 is present.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	I2C1	RO	1	I2C Module 1 Present When set, indicates that I2C module 1 is present.
13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	RO	1	I2C Module 0 Present When set, indicates that I2C module 0 is present.
11:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	QE11	RO	1	QE1 Module 1 Present When set, indicates that QE1 module 1 is present.
8	QE10	RO	1	QE1 Module 0 Present When set, indicates that QE1 module 0 is present.
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SSI1	RO	1	SSI Module 1 Present When set, indicates that SSI module 1 is present.
4	SSI0	RO	1	SSI Module 0 Present When set, indicates that SSI module 0 is present.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	UART2	RO	1	UART Module 2 Present When set, indicates that UART module 2 is present.
1	UART1	RO	1	UART Module 1 Present When set, indicates that UART module 1 is present.

Bit/Field	Name	Type	Reset	Description
0	UART0	RO	1	UART Module 0 Present When set, indicates that UART module 0 is present.

## Register 20: Device Capabilities 3 (DC3), offset 0x018

This register is predefined by the part and can be used to verify features. If any bit is clear in this register, the module is not present. The corresponding bit in the RCGC0, SCGC0, and DCGC0 registers cannot be set.

## Register 24: Device Capabilities 7 (DC7), offset 0x028

This register is predefined by the part and can be used to verify uDMA channel features. A 1 indicates the channel is available on this device; a 0 that the channel is only available on other devices in the family. Most channels have primary and alternate assignments. If the primary function is not available on this microcontroller, the alternate function becomes the primary function. If the alternate function is not available, the primary function is the only option.

Bit/Field	Name	Type	Reset	Description
31	reserved-31	RO	1	Reserved Reserved for uDMA channel 31.
30	DMACH30	RO	1	SW When set, indicates uDMA channel 30 is available for software transfers.
29	DMACH29	RO	1	I2S0_TX / CAN1_TX When set, indicates uDMA channel 29 is available and connected to the transmit path of I2S module 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of CAN module 1 transmit.
28	DMACH28	RO	1	I2S0_RX / CAN1_RX When set, indicates uDMA channel 28 is available and connected to the receive path of I2S module 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of CAN module 1 receive.
27	DMACH27	RO	1	CAN1_TX / ADC1_SS3 When set, indicates uDMA channel 27 is available and connected to the transmit path of CAN module 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of ADC module 1 Sample Sequencer 3.
26	DMACH26	RO	1	CAN1_RX / ADC1_SS2 When set, indicates uDMA channel 26 is available and connected to the receive path of CAN module 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of ADC module 1 Sample Sequencer 2.

Bit/Field	Name	Type	Reset	Description
25	DMACH25	RO	1	SSI1_TX / ADC1_SS1 When set, indicates uDMA channel 25 is available and connected to the transmit path of SSI module 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of ADC module 1 Sample Sequencer 1.
24	DMACH24	RO	1	SSI1_RX / ADC1_SS0 When set, indicates uDMA channel 24 is available and connected to the receive path of SSI module 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of ADC module 1 Sample Sequencer 0.
23	DMACH23	RO	1	UART1_TX / CAN2_TX When set, indicates uDMA channel 23 is available and connected to the transmit path of UART module 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of CAN module 2 transmit.
22	DMACH22	RO	1	UART1_RX / CAN2_RX When set, indicates uDMA channel 22 is available and connected to the receive path of UART module 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of CAN module 2 receive.
21	DMACH21	RO	1	Timer1B / EPI0_TX When set, indicates uDMA channel 21 is available and connected to Timer 1B. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of EPI module 0 transmit.
20	DMACH20	RO	1	Timer1A / EPI0_RX When set, indicates uDMA channel 20 is available and connected to Timer 1A. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of EPI module 0 receive.
19	DMACH19	RO	1	Timer0B / Timer1B When set, indicates uDMA channel 19 is available and connected to Timer 0B. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 1B.
18	DMACH18	RO	1	Timer0A / Timer1A When set, indicates uDMA channel 18 is available and connected to Timer 0A. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 1A.
17	DMACH17	RO	1	ADC0_SS3 When set, indicates uDMA channel 17 is available and connected to ADC module 0 Sample Sequencer 3.

Bit/Field	Name	Type	Reset	Description
16	DMACH16	RO	1	ADC0_SS2 When set, indicates uDMA channel 16 is available and connected to ADC module 0 Sample Sequencer 2.
15	DMACH15	RO	1	ADC0_SS1 / Timer2B When set, indicates uDMA channel 15 is available and connected to ADC module 0 Sample Sequencer 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 2B.
14	DMACH14	RO	1	ADC0_SS0 / Timer2A When set, indicates uDMA channel 14 is available and connected to ADC module 0 Sample Sequencer 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 2A.
13	DMACH13	RO	1	CAN0_TX / UART2_TX When set, indicates uDMA channel 13 is available and connected to the transmit path of CAN module 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of UART module 2 transmit.
12	DMACH12	RO	1	CAN0_RX / UART2_RX When set, indicates uDMA channel 12 is available and connected to the receive path of CAN module 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of UART module 2 receive.
11	DMACH11	RO	1	SSI0_TX / UART1_TX When set, indicates uDMA channel 11 is available and connected to the transmit path of SSI module 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of UART module 1 transmit.
10	DMACH10	RO	1	SSI0_RX / UART1_RX When set, indicates uDMA channel 10 is available and connected to the receive path of SSI module 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of UART module 1 receive.
9	DMACH9	RO	1	UART0_TX / SSI1_TX When set, indicates uDMA channel 9 is available and connected to the transmit path of UART module 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of SSI module 1 transmit.
8	DMACH8	RO	1	UART0_RX / SSI1_RX When set, indicates uDMA channel 8 is available and connected to the receive path of UART module 0. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of SSI module 1 receive.

Bit/Field	Name	Type	Reset	Description
7	DMACH7	RO	1	ETH_TX / Timer2B  When set, indicates uDMA channel 7 is available and connected to the transmit path of the Ethernet module. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 2B.
6	DMACH6	RO	1	ETH_RX / Timer2A  When set, indicates uDMA channel 6 is available and connected to the receive path of the Ethernet module. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 2A.
5	DMACH5	RO	1	USB_EP3_TX / Timer2B  When set, indicates uDMA channel 5 is available and connected to the transmit path of USB endpoint 3. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 2B.
4	DMACH4	RO	1	USB_EP3_RX / Timer2A  When set, indicates uDMA channel 4 is available and connected to the receive path of USB endpoint 3. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 2A.
3	DMACH3	RO	1	USB_EP2_TX / Timer3B  When set, indicates uDMA channel 3 is available and connected to the transmit path of USB endpoint 2. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 3B.
2	DMACH2	RO	1	USB_EP2_RX / Timer3A  When set, indicates uDMA channel 2 is available and connected to the receive path of USB endpoint 2. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of Timer 3A.
1	DMACH1	RO	1	USB_EP1_TX / UART2_TX  When set, indicates uDMA channel 1 is available and connected to the transmit path of USB endpoint 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of UART module 2 transmit.
0	DMACH0	RO	1	USB_EP1_RX / UART2_RX  When set, indicates uDMA channel 0 is available and connected to the receive path of USB endpoint 1. If the corresponding bit in the <b>DMACHALT</b> register is set, the channel is connected instead to the alternate channel assignment of UART module 2 receive.

## Register 25: Device Capabilities 8 ADC Channels (DC8), offset 0x02C

This register is predefined by the part and can be used to verify features.

## Register 28: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled (saving power). If the module is unlocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## Register 31: Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Bit/Field	Name	Type	Reset	Description
31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30	EPI0	R/W	0	EPI0 Clock Gating  This bit controls the clock gating for EPI module 0. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.
29	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28	I2S0	R/W	0	I2S0 Clock Gating  This bit controls the clock gating for I2S module 0. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.
27	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
26	COMP2	R/W	0	<b>Analog Comparator 2 Clock Gating</b>  This bit controls the clock gating for analog comparator 2. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
25	COMP1	R/W	0	<b>Analog Comparator 1 Clock Gating</b>  This bit controls the clock gating for analog comparator 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
24	COMP0	R/W	0	<b>Analog Comparator 0 Clock Gating</b>  This bit controls the clock gating for analog comparator 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	R/W	0	<b>Timer 3 Clock Gating Control</b>  This bit controls the clock gating for General-Purpose Timer module 3. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
18	TIMER2	R/W	0	<b>Timer 2 Clock Gating Control</b>  This bit controls the clock gating for General-Purpose Timer module 2. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
17	TIMER1	R/W	0	<b>Timer 1 Clock Gating Control</b>  This bit controls the clock gating for General-Purpose Timer module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
16	TIMER0	R/W	0	<b>Timer 0 Clock Gating Control</b>  This bit controls the clock gating for General-Purpose Timer module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	I2C1	R/W	0	<b>I2C1 Clock Gating Control</b>  This bit controls the clock gating for I2C module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

Bit/Field	Name	Type	Reset	Description
13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control  This bit controls the clock gating for I2C module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
11:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	QE11	R/W	0	QE11 Clock Gating Control  This bit controls the clock gating for QE1 module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
8	QE10	R/W	0	QE10 Clock Gating Control  This bit controls the clock gating for QE1 module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SSI1	R/W	0	SSI1 Clock Gating Control  This bit controls the clock gating for SSI module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
4	SSI0	R/W	0	SSI0 Clock Gating Control  This bit controls the clock gating for SSI module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	UART2	R/W	0	UART2 Clock Gating Control  This bit controls the clock gating for UART module 2. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

Bit/Field	Name	Type	Reset	Description
1	UART1	R/W	0	UART1 Clock Gating Control  This bit controls the clock gating for UART module 1. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.
0	UART0	R/W	0	UART0 Clock Gating Control  This bit controls the clock gating for UART module 0. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.

## Register 32: Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

29	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28	I2S0	R/W	0	I2S0 Clock Gating  This bit controls the clock gating for I2S module 0. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.
27	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
26	COMP2	R/W	0	<b>Analog Comparator 2 Clock Gating</b>  This bit controls the clock gating for analog comparator 2. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
25	COMP1	R/W	0	<b>Analog Comparator 1 Clock Gating</b>  This bit controls the clock gating for analog comparator 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
24	COMP0	R/W	0	<b>Analog Comparator 0 Clock Gating</b>  This bit controls the clock gating for analog comparator 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	R/W	0	<b>Timer 3 Clock Gating Control</b>  This bit controls the clock gating for General-Purpose Timer module 3. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
18	TIMER2	R/W	0	<b>Timer 2 Clock Gating Control</b>  This bit controls the clock gating for General-Purpose Timer module 2. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
17	TIMER1	R/W	0	<b>Timer 1 Clock Gating Control</b>  This bit controls the clock gating for General-Purpose Timer module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
16	TIMER0	R/W	0	<b>Timer 0 Clock Gating Control</b>  This bit controls the clock gating for General-Purpose Timer module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	I2C1	R/W	0	<b>I2C1 Clock Gating Control</b>  This bit controls the clock gating for I2C module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

Bit/Field	Name	Type	Reset	Description
13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control  This bit controls the clock gating for I2C module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
11:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	QE11	R/W	0	QE11 Clock Gating Control  This bit controls the clock gating for QE1 module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
8	QE10	R/W	0	QE10 Clock Gating Control  This bit controls the clock gating for QE1 module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SSI1	R/W	0	SSI1 Clock Gating Control  This bit controls the clock gating for SSI module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
4	SSI0	R/W	0	SSI0 Clock Gating Control  This bit controls the clock gating for SSI module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	UART2	R/W	0	UART2 Clock Gating Control  This bit controls the clock gating for UART module 2. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

Bit/Field	Name	Type	Reset	Description
1	UART1	R/W	0	UART1 Clock Gating Control  This bit controls the clock gating for UART module 1. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.
0	UART0	R/W	0	UART0 Clock Gating Control  This bit controls the clock gating for UART module 0. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.

## Register 33: Deep-Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled (saving power). If the module is unclocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Bit/Field	Name	Type	Reset	Description
13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control  This bit controls the clock gating for I2C module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
11:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	QE11	R/W	0	QE11 Clock Gating Control  This bit controls the clock gating for QE1 module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
8	QE10	R/W	0	QE10 Clock Gating Control  This bit controls the clock gating for QE1 module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SSI1	R/W	0	SSI1 Clock Gating Control  This bit controls the clock gating for SSI module 1. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
4	SSI0	R/W	0	SSI0 Clock Gating Control  This bit controls the clock gating for SSI module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	UART2	R/W	0	UART2 Clock Gating Control  This bit controls the clock gating for UART module 2. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

Bit/Field	Name	Type	Reset	Description
1	UART1	R/W	0	UART1 Clock Gating Control  This bit controls the clock gating for UART module 1. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.
0	UART0	R/W	0	UART0 Clock Gating Control  This bit controls the clock gating for UART module 0. If set, the module receives a clock and functions. Otherwise, the module is unclocked and disabled. If the module is unclocked, a read or write to the module generates a bus fault.

## Register 34: Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108

This register controls the clock gating logic in normal Run mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled (saving power). If the module is unlocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Bit/Field	Name	Type	Reset	Description
31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30	EPHY0	R/W	0	PHY0 Clock Gating Control  This bit controls the clock gating for Ethernet PHY layer 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
29	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28	EMAC0	R/W	0	MAC0 Clock Gating Control  This bit controls the clock gating for Ethernet MAC layer 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
27:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
16	USB0	R/W	0	<b>USB0 Clock Gating Control</b>  This bit controls the clock gating for USB module 0. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
15:14	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13	UDMA	R/W	0	<b>Micro-DMA Clock Gating Control</b>  This bit controls the clock gating for micro-DMA. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
12:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	GPIOJ	R/W	0	<b>Port J Clock Gating Control</b>  This bit controls the clock gating for Port J. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
7	GPIOH	R/W	0	<b>Port H Clock Gating Control</b>  This bit controls the clock gating for Port H. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
6	GPIOG	R/W	0	<b>Port G Clock Gating Control</b>  This bit controls the clock gating for Port G. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
5	GPIOF	R/W	0	<b>Port F Clock Gating Control</b>  This bit controls the clock gating for Port F. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
4	GPIOE	R/W	0	<b>Port E Clock Gating Control</b>  Port E Clock Gating Control. This bit controls the clock gating for Port E. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
3	GPIOD	R/W	0	<b>Port D Clock Gating Control</b>  Port D Clock Gating Control. This bit controls the clock gating for Port D. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

---

Bit/Field	Name	Type	Reset	Description
2	GPIOC	R/W	0	Port C Clock Gating Control  This bit controls the clock gating for Port C. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
1	GPIOB	R/W	0	Port B Clock Gating Control  This bit controls the clock gating for Port B. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.
0	GPIOA	R/W	0	Port A Clock Gating Control  This bit controls the clock gating for Port A. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled. If the module is unlocked, a read or write to the module generates a bus fault.

## Register 35: Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118

This register controls the clock gating logic in Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled (saving power). If the module is unlocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

## Register 36: Deep Sleep Mode Clock Gating Control Register 2 (DCGC2), offset 0x128

This register controls the clock gating logic in Deep-Sleep mode. Each bit controls a clock enable for a given interface, function, or module. If set, the module receives a clock and functions. Otherwise, the module is unlocked and disabled (saving power). If the module is unlocked, reads or writes to the module generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional modules are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or modules to control. This configuration is implemented to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30	EPI0	R/W	0	EPI0 Reset Control  When this bit is set, EPI module 0 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
29	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28	I2S0	R/W	0	I2S0 Reset Control  When this bit is set, I2S module 0 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
27	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
26	COMP2	R/W	0	Analog Comp 2 Reset Control  When this bit is set, Analog Comparator module 2 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
25	COMP1	R/W	0	Analog Comp 1 Reset Control  When this bit is set, Analog Comparator module 1 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
24	COMP0	R/W	0	Analog Comp 0 Reset Control  When this bit is set, Analog Comparator module 0 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.

Bit/Field	Name	Type	Reset	Description
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	R/W	0	Timer 3 Reset Control  Timer 3 Reset Control. When this bit is set, General-Purpose Timer module 3 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
18	TIMER2	R/W	0	Timer 2 Reset Control  When this bit is set, General-Purpose Timer module 2 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
17	TIMER1	R/W	0	Timer 1 Reset Control  When this bit is set, General-Purpose Timer module 1 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
16	TIMER0	R/W	0	Timer 0 Reset Control  When this bit is set, General-Purpose Timer module 0 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	I2C1	R/W	0	I2C1 Reset Control  When this bit is set, I2C module 1 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Reset Control  When this bit is set, I2C module 0 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
11:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	QE11	R/W	0	QE11 Reset Control  When this bit is set, QE1 module 1 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
8	QE10	R/W	0	QE10 Reset Control  When this bit is set, QE1 module 0 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.

Bit/Field	Name	Type	Reset	Description
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SSI1	R/W	0	SSI1 Reset Control  When this bit is set, SSI module 1 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
4	SSI0	R/W	0	SSI0 Reset Control  When this bit is set, SSI module 0 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	UART2	R/W	0	UART2 Reset Control  When this bit is set, UART module 2 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
1	UART1	R/W	0	UART1 Reset Control  When this bit is set, UART module 1 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
0	UART0	R/W	0	UART0 Reset Control  When this bit is set, UART module 0 is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.

## Register 39: Software Reset Control 2 (SRCR2), offset 0x048

This register allows individual modules to be reset. Writes to this register are masked by the bits in the **Device Capabilities 4 (DC4)** register.

Bit/Field	Name	Type	Reset	Description
12:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	GPIOJ	R/W	0	Port J Reset Control  When this bit is set, Port J module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
7	GPIOH	R/W	0	Port H Reset Control  When this bit is set, Port H module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
6	GPIOG	R/W	0	Port G Reset Control  When this bit is set, Port G module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
5	GPIOF	R/W	0	Port F Reset Control  When this bit is set, Port F module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
4	GPIOE	R/W	0	Port E Reset Control  When this bit is set, Port E module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
3	GPIOD	R/W	0	Port D Reset Control  When this bit is set, Port D module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
2	GPIOC	R/W	0	Port C Reset Control  When this bit is set, Port C module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
1	GPIOB	R/W	0	Port B Reset Control  When this bit is set, Port B module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.
0	GPIOA	R/W	0	Port A Reset Control  When this bit is set, Port A module is reset. All internal data is lost and the registers are returned to their reset states. This bit must be manually cleared after being set.

## 7 Internal Memory

The LM3S9792 microcontroller comes with 64 KB of bit-banded SRAM, internal ROM, and 128 KB of Flash memory. The Flash controller provides a user-friendly interface, making Flash programming a simple task. Flash protection can be applied to the Flash memory on a 2-KB block basis.

### 7.1 Block Diagram

Figure 7-1 on page 195 illustrates the Flash functions. The dashed boxes in the figure indicate registers residing in the System Control module rather than the Flash Control module.

Figure 7-1. Flash Block Diagram

## 7.2 Functional Description

This section describes the functionality of the SRAM, ROM, and Flash memories.

### 7.2.1 SRAM

**Note:** The SRAM is implemented using two 32-bit wide SRAM banks (separate SRAM arrays). The banks are partitioned such that one bank contains all even words (the even bank) and the other contains all odd words (the odd bank). A write access that is followed immediately by a read access to the same bank incurs a stall of a single clock cycle. However, a write to one bank followed by a read of the other bank can occur in successive clock cycles without incurring any delay.

The internal SRAM of the Stellaris<sup>®</sup> devices is located at address 0x2000.0000 of the device memory map. To reduce the number of time consuming read-modify-write (RMW) operations, ARM has introduced *bit-banding* technology in the Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation. The bit-band base is located at address 0x2200.0000.

The bit-band alias is calculated by using the formula:

$$\text{bit-band alias} = \text{bit-band base} + (\text{byte offset} * 32) + (\text{bit number} * 4)$$

For example, if bit 3 at address 0x2000.1000 is to be modified, the bit-band alias is calculated as:

$$0x2200.0000 + (0x1000 * 32) + (3 * 4) = 0x2202.000C$$

With the alias address calculated, an instruction performing a read/write to address 0x2202.000C allows direct access to only bit 3 of the byte at address 0x2000.1000.

For details about bit-banding, please refer to Chapter 4, “Memory Map” in the *ARM<sup>®</sup> Cortex<sup>™</sup>-M3 Technical Reference Manual*.

### 7.2.2 ROM

The internal ROM of the Stellaris<sup>®</sup> device is located at address 0x0100.0000 of the device memory map. The ROM contains the following components:

- Stellaris<sup>®</sup> Boot Loader and vector table (see “Boot Loader” on page 1022)
- Stellaris<sup>®</sup> Peripheral Driver Library (DriverLib) release for product-specific peripherals and interfaces (see “ROM DriverLib Functions” on page 1027)
- Advanced Encryption Standard (AES) cryptography tables (see “Advance Encryption Standard and Cyclic Redundancy Check Software in ROM” on page 1047)
- Cyclic Redundancy Check (CRC) error detection functionality (see “Advance Encryption Standard and Cyclic Redundancy Check Software in ROM” on page 1047)

### 7.2.3 Flash Memory

The Flash is organized as a set of 1-KB blocks that can be individually erased. An individual 32-bit word can be programmed to change bits from 1 to 0. In addition, a write buffer provides the ability to concurrently program 32 continuous words in Flash memory. Erasing a block causes the entire contents of the block to be reset to all 1s. The 1-KB blocks are paired into sets of 2-KB blocks that can be individually protected. The protection allows blocks to be marked as read-only or execute-only,

providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

The Flash memory controller has a prefetch buffer that is automatically used when the CPU frequency is greater than 50 MHz. The prefetch buffer fetches two 32-bit words per clock allowing Flash memory to be read with no wait states while code is executing linearly. Branches incur a single wait state.

### 7.2.3.1 Flash Memory Protection

The user is provided two forms of Flash protection per 2-KB Flash block in two pairs of 32-bit wide registers. The policy for each protection form is controlled by individual bits (per policy per block) in the **FMPPEn** and **FMPREn** registers.

- **Flash Memory Protection Program Enable (FMPPEn):** If a bit is set, the corresponding block may be programmed (written) or erased. If a bit is cleared, the corresponding block may not be changed.
- **Flash Memory Protection Read Enable (FMPREn):** If a bit is set, the corresponding block may be executed or read by software or debuggers. If a bit is cleared, the corresponding block may only be executed, and contents of the memory block are prohibited from being accessed as data.

The policies may be combined as shown in Table 7-1 on page 197.

**Table 7-1. Flash Protection Policy Combinations**

FMPPEn	FMPREn	Protection
0	0	Execute-only protection. The block may only be executed and may not be written or erased. This mode is used to protect code.
1	0	The block may be written, erased or executed, but not read. This combination is unlikely to be used.
0	1	Read-only protection. The block may be read or executed but may not be written or erased. This mode is used to lock the block from further modification while allowing any read or execute access.
1	1	No protection. The block may be written, erased, executed or read.

An access that attempts to program or erase a program-protected block is prohibited. An access that attempts to read a read-protected block is prohibited. Such accesses return data of all 0s. A controller interrupt may be optionally generated whenever an attempt is made to improperly access the Flash memory (by setting the **AMASK** bit in the **Flash Controller Interrupt Mask (FCIM)** register) to alert software developers of poorly behaving software during the development and debug phases.

The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. These settings create a policy of open access and programmability. The register bits may be changed by clearing the specific register bit. The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The changes are committed using the **Flash Memory Control (FMC)** register. Details on programming these bits are discussed in “Nonvolatile Register Programming” on page 199.

## 7.3 Flash Memory Initialization and Configuration

### 7.3.1 Flash Programming

The Stellaris<sup>®</sup> devices provide a user-friendly interface for Flash programming. All erase/program operations are handled via three registers: **Flash Memory Address (FMA)**, **Flash Memory Data**

(**FMD**), and **Flash Memory Control (FMC)**. Note that if the debug capabilities of the microcontroller have been deactivated, resulting in a "locked" state, a recovery sequence must be performed in order to reactivate the debug module. See "Recovering a "Locked" Microcontroller" on page 83.

### 7.3.1.1 To program a 32-bit word

1. Write source data to the **FMD** register.
2. Write the target address to the **FMA** register.
3. Write the Flash write key and the `WRITE` bit (a value of 0xA442.0001) to the **FMC** register.
4. Poll the **FMC** register until the `WRITE` bit is cleared.

---

**Important:** To ensure proper operation, two writes to the same word must be separated by an `ERASE`.

---

### 7.3.1.2 To perform an erase of a 1-KB page

1. Write the page address to the **FMA** register.
2. Write the Flash write key and the `ERASE` bit (a value of 0xA442.0002) to the **FMC** register.
3. Poll the **FMC** register until the `ERASE` bit is cleared.

### 7.3.1.3 To perform a mass erase of the Flash

1. Write the Flash write key and the `MERASE` bit (a value of 0xA442.0004) to the **FMC** register.
2. Poll the **FMC** register until the `MERASE` bit is cleared.

## 7.3.2 32-Word Flash Write Buffer

A 32-word write buffer provides the capability to perform faster write accesses to the Flash memory by concurrently programming 32 words with a single buffered Flash write operation. The buffered Flash write operation takes the same amount of time as the single word write operation controlled by bit 0 in the **FMC** register. The data for the buffered write is written to the **Flash Write Buffer (FWBn)** registers.

The registers are 32-word aligned with Flash memory, and therefore the register **FWB0** corresponds with the address in **FMA** where bits [6:0] of **FMA** are all 0. **FWB1** corresponds with the address in **FMA** + 0x4 and so on. Only the **FWBn** registers that have been updated since the previous buffered Flash write operation are written. The **Flash Write Buffer Valid (FWBVAL)** register shows which registers have been written since the last buffered Flash write operation. This register contains a bit for each of the 32 **FWBn** registers, where bit[n] of **FWBVAL** corresponds to **FWBn**. The **FWBn** register has been updated if the corresponding bit in the **FWBVAL** register is set.

### 7.3.2.1 To program 32 words with a single buffered Flash write operation

1. Write the source data to the **FWBn** registers.
2. Write the target address to the **FMA** register. This must be a 32-word aligned address (that is, bits [6:0] in **FMA** must be 0s).
3. Write the Flash write key and the `WRBUF` bit (a value of 0xA442.0001) to the **FMC2** register.

4. Poll the **FMC2** register until the `WRBUF` bit is cleared.

### 7.3.3 Nonvolatile Register Programming

This section discusses how to update registers that are resident within the Flash memory itself. These registers exist in a separate space from the main Flash array and are not affected by an ERASE or MASS ERASE operation. These nonvolatile registers are updated using the `COMT` bit in the **FMC** register to activate a write operation. With the exception of the **USER\_DBG** register, the settings in these registers can be tested before committing them to Flash memory.

For the **USER\_DBG** register, the data to be written is loaded into the **FMD** register before it is committed. The **FMD** register is read only and does not allow the **USER\_DBG** operation to be tried before committing it to nonvolatile memory.

**Important:** These registers can only have bits changed from 1 to 0 by user programming, but can be restored to their factory default values only by performing the sequence described in "Recovering a "Locked" Microcontroller" on page 83. The mass erase of the main Flash array caused by the sequence is performed prior to restoring these registers.

In addition, the **USER\_REG0**, **USER\_REG1**, **USER\_REG2**, **USER\_REG3**, and **USER\_DBG** registers each use bit 31 (`NW`) to indicate that they are available for user write. These five registers can only be committed once whereas the Flash protection registers may be committed multiple times. Table 7-2 on page 199 provides the **FMA** address required for commitment of each of the registers and the source of the data to be written when the **FMC** register is written with a value of `0xA442.0008`. After writing the `COMT` bit, the user may poll the **FMC** register to wait for the commit operation to complete.

**Table 7-2. User-Programmable Flash Resident Registers**

Register to be Committed	FMA Value	Data Source
FMPRE0	0x0000.0000	FMPRE0
FMPRE1	0x0000.0002	FMPRE1
FMPPE0	0x0000.0001	FMPPE0
FMPPE1	0x0000.0003	FMPPE1
USER_REG0	0x8000.0000	USER_REG0
USER_REG1	0x8000.0001	USER_REG1
USER_REG2	0x8000.0002	USER_REG2
USER_REG3	0x8000.0003	USER_REG3
USER_DBG	0x7510.0000	FMD

## 7.4 Register Map

Table 7-3 on page 200 lists the ROM Controller register and the Flash memory and control registers. The offset listed is a hexadecimal increment to the register's address. The **FMA**, **FMD**, **FMC**, **FCRIS**, **FCIM**, **FCMISC**, **FMC2**, **FWBVAL**, and **FWBn** register offsets are relative to the Flash control base address of `0x400F.D000`. The ROM and Flash protection register offsets are relative to the System Control base address of `0x400F.E000`.

Table 7-3. Flash Register Map

Offset	Name	Type	Reset	Description	See page

## 7.5 Flash Register Descriptions (Flash Control Offset)

This section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the Flash control base address of 0x400F.D000.

## Register 1: Flash Memory Address (FMA), offset 0x000

During a write operation, this register contains a 4-byte-aligned address and specifies where the data is written. During erase operations, this register contains a 1 KB-aligned address and specifies which page is erased. Note that the alignment requirements must be met by software or the results of the operation are unpredictable.

### Flash Memory Address (FMA)

Base 0x400F.D000

Offset 0x000

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16:0	OFFSET	R/W	0x0	Address Offset  Address offset in Flash where operation is performed, except for nonvolatile registers (see "Nonvolatile Register Programming" on page 199 for details on values for this field).

## Register 2: Flash Memory Data (FMD), offset 0x004

This register contains the data to be written during the programming cycle or read during the read cycle. Note that the contents of this register are undefined for a read access of an execute-only block. This register is not used during erase cycles.

### Flash Memory Data (FMD)

### Register 3: Flash Memory Control (FMC), offset 0x008

When this register is written, the Flash controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 201). If the access is a write access, the data contained in the **Flash Memory Data (FMD)** register (see page 202) is written to the specified address.

This register must be the final register written and initiates the memory operation. The four control bits in the lower byte of this register are used to initiate memory operations.

Care must be taken not to set multiple control bits as the results of such an operation are unpredictable.

0	The <code>ARIS</code> interrupt is suppressed and not sent to the interrupt controller.							

## Register 6: Flash Controller Masked Interrupt Status and Clear (FCMISC), offset 0x014

This register provides two functions. First, it reports the cause of an interrupt by indicating which interrupt source or sources are signalling the interrupt. Second, it serves as the method to clear the interrupt reporting.

## Register 7: Flash Memory Control 2 (FMC2), offset 0x020

When this register is written, the Flash controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 201). If the access is a write access, the data contained in the **Flash Write Buffer (FWB)** registers is written.

This register must be the final register written as it initiates the memory operation.

### Flash Memory Control 2 (FMC2)

Base 0x400F.D000  
 Offset 0x020  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	WRKEY	WO	0x0000	Flash Write Key  This field contains a write key, which is used to minimize the incidence of accidental Flash writes. The value 0xA442 must be written into this field for a write to occur. Writes to the <b>FMC2</b> register without this <b>WRKEY</b> value are ignored. A read of this field returns the value 0.
15:1	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	WRBUF	R/W	0	Buffered Flash Write

This bit is used to start a buffered Flash write to Flash Memory.

#### Value Description

- 1 Set this bit to write the data stored in the **FWBn** registers to the location specified by the contents of the **FMA** register.  
  
When read, a 1 indicates that the previous buffered Flash write access is not complete.
- 0 A write of 0 has no effect on the state of this bit.  
  
When read, a 0 indicates that the previous buffered Flash write access is complete.

A buffered Flash write can take up to 4 ms.

## Register 8: Flash Write Buffer Valid (FWBVAL), offset 0x030

This register provides a bitwise status of which **FWB<sub>n</sub>** registers have been written by the processor since the last write of the Flash write buffer. The entries with a 1 are written on the next write of the Flash write buffer. This register is cleared after the write operation by hardware. A protection violation on the write operation also clears this status.

Software can program the same 32 words to various Flash memory locations by setting the **FWB<sub>[n]</sub>** bits after they are cleared by the write operation. The next write operation then uses the same data as the previous one. In addition, if a **FWB<sub>n</sub>** register change should not be written to Flash memory, software can clear the corresponding **FWB<sub>[n]</sub>** bit to preserve the existing data when the next write operation occurs.

### Flash Write Buffer Valid (FWBVAL)

Base 0x400F.D000

Offset 0x030

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	FWB[n]	R/W	0x0	Flash Write Buffer

#### Value Description

- |   |  |
|---|--|
| 1 | The corresponding <b>FWB<sub>n</sub></b> register has been updated since the last buffer write operation and is ready to be written to Flash memory. |
| 0 | The corresponding <b>FWB<sub>n</sub></b> register has no new data to be written.   |

Bit 0 corresponds to **FWB0**, offset 0x100, and bit 31 corresponds to **FWB31**, offset 0x13C.

### Register 9: Flash Write Buffer n (FWBn), offset 0x100 - 0x13C

These 32 registers hold the contents of the data to be written into the Flash on a buffered Flash write operation. The offset selects one of the 32-bit registers. Only **FWBn** registers that have been updated since the preceding buffered Flash write operation are written into the Flash, so it is not necessary to write the entire bank of registers in order to write 1 or 2 words. The **FWBn** registers are written into the Flash with the **FWB0** register corresponding to the address contained in **FMA**. **FWB1** is written to the address **FMA+0x4** etc. Note that only data bits that are 0 result in the Flash memory being modified. A data bit that is 1 leaves the content of the Flash memory bit at its previous value.

#### Flash Write Buffer n (FWBn)

Base 0x400F.D000  
 Offset 0x100 - 0x13C  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATA	R/W	0x0000.0000	Data

Data to be written into the Flash.

## 7.6 Memory Register Descriptions (System Control Offset)

The remainder of this section lists and describes the registers that reside in Flash memory, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

**Register 10: ROM Control (RMCTL), offset 0x0F0**

This register provides control of the ROM controller state. This register offset is relative to the System Control base address of 0x400F.E000.

**ROM Control (RMCTL)**

Base 0x400F.E000

Offset 0x0F0

Type R/W1C, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	BA	R/W1C	-	Boot Alias

Upon reset, the system control module checks the first two words of the Flash memory to see if it has been programmed. If the first two words of Flash memory contain 0xFFFF.FFFF then it has not yet been programmed, and this bit is then set by hardware so that the on-chip ROM appears at address 0x0.

**Value Description**

- 1 The microcontroller's ROM appears at address 0x0. This bit is set automatically if the first two words of the Flash memory contain 0xFFFF.FFFF.
- 0 The Flash memory is at address 0x0.

This bit is cleared by writing a 1 to this bit position.

### Register 11: ROM Version Register (RMVER), offset 0x0F4

**Note:** Offset is relative to System Control base address of 0x400FE000.

A 32-bit read-only register containing the ROM content version information.

#### ROM Version Register (RMVER)

Base 0x400F.E000  
 Offset 0x0F4  
 Type RO, reset 0x0202.5400

Bit/Field	Name	Type	Reset	Description
31:24	CONT	RO	0x02	ROM Contents  Value Description 0x02 Stellaris Boot Loader & DriverLib with AES
23:16	SIZE	RO	0x02	ROM Size  This field encodes the size of the ROM.  Value Description 0x02 Stellaris Boot Loader & DriverLib with AES, ethernet
15:8	VER	RO	0x54	ROM Version
7:0	REV	RO	0x0	ROM Revision

## Register 12: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200

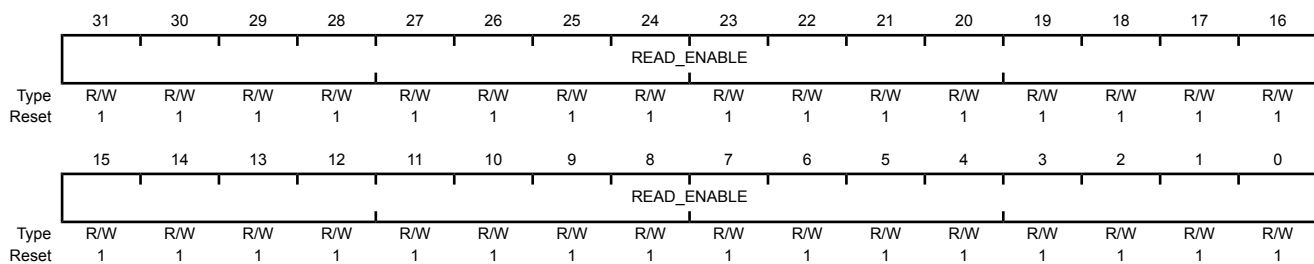

**Note:** This register is aliased for backwards compatibility.

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

### Flash Memory Protection Read Enable 0 (FMPRE0)

Base 0x400F.E000  
 Offset 0x130 and 0x200  
 Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0xFFFFFFFF	Flash Read Enable. Enables 2-KB Flash memory blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
	Value	Description		
	0xFFFFFFFF	Enables 128 KB of Flash memory.		

### Register 13: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400

**Note:** This register is aliased for backwards compatability.

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREN** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

#### Flash Memory Protection Program Enable 0 (FMPPE0)

Base 0x400F.E000  
 Offset 0x134 and 0x400  
 Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	PROG_ENABLE	R/W	0xFFFFFFFF	Flash Programming Enable

Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value	Description
0xFFFFFFFF	Enables 128 KB of Flash memory.

### Register 14: User Debug (USER\_DBG), offset 0x1D0

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register provides a write-once mechanism to disable external debugger access to the device in addition to 27 additional bits of user-defined data. The `DBG0` bit (bit 0) is set to 0 from the factory and the `DBG1` bit (bit 1) is set to 1, which enables external debuggers. Changing the `DBG1` bit to 0 disables any external debugger access to the device permanently, starting with the next power-up cycle of the device. The `NOTWRITTEN` bit (bit 31) indicates that the register is available to be written and is controlled through hardware to ensure that the register is only written once.

31	NW	R/W	1	User Debug Not Written. When set, this bit specifies that this 32-bit register has not been written. When clear, this bit specifies that this register has been written and may not be written again.
30:2	DATA	R/W	0x1FFFFFFF	User Data. Contains the user data value. This field is initialized to all 1s and can only be written once.
1	DBG1	R/W	1	Debug Control 1. The <code>DBG1</code> bit must be 1 and <code>DBG0</code> must be 0 for debug to be available.
0	DBG0	R/W	0	Debug Control 0. The <code>DBG1</code> bit must be 1 and <code>DBG0</code> must be 0 for debug to be available.

### Register 15: User Register 0 (USER\_REG0), offset 0x1E0

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register provides 31 bits of user-defined data that is non-volatile and can only be written once. Bit 31 indicates that the register is available to be written and is controlled through hardware to ensure that the register is only written once. The write-once characteristics of this register are useful for keeping static information like communication addresses that need to be unique per part and would otherwise require an external EEPROM or other non-volatile device.

#### User Register 0 (USER\_REG0)

Base 0x400F.E000

Offset 0x1E0

### Register 19: Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

#### Flash Memory Protection Read Enable 1 (FMPRE1)

Base 0x400F.E000  
 Offset 0x204  
 Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0xFFFFFFFF	Flash Read Enable. Enables 2-KB Flash memory blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value Description
				0xFFFFFFFF Enables 128 KB of Flash memory.

**Register 20: Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208**

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

## Flash Memory Protection Read Enable 2 (FMPRE2)

Base 0x400F.E000

Offset 0x208

Type R/W, reset 0x0000.0000

### Register 21: Flash Memory Protection Read Enable 3 (FMPRE3), offset 0x20C

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

#### Flash Memory Protection Read Enable 3 (FMPRE3)

Base 0x400F.E000  
 Offset 0x20C  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0x00000000	Flash Read Enable. Enables 2-KB Flash memory blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value Description
			0x00000000	Enables 128 KB of Flash memory.

## Register 22: Flash Memory Protection Program Enable 1 (FMPPE1), offset 0x404

**Note:** Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPPE<sub>n</sub>** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPPE<sub>n</sub>** and **FMPPE<sub>n</sub>** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

### Flash Memory Protection Program Enable 1 (FMPPE1)

Base 0x400F.E000

Offset 0x404

0x00000000	Enables 128 KB of Flash memory.

## 8 Micro Direct Memory Access ( $\mu$ DMA)

The LM3S9792 microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA ( $\mu$ DMA). The  $\mu$ DMA controller provides a way to offload data transfer tasks from the Cortex-M3 processor, allowing for more efficient use of the processor and the expanded available bus bandwidth. The  $\mu$ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The  $\mu$ DMA controller provides the following features:

- ARM PrimeCell® 32-channel configurable  $\mu$ DMA controller
- Support for multiple transfer modes
  - Memory-to-memory, memory-to-peripheral, peripheral-to-memory
  - Basic for simple transfer scenarios
  - Ping-pong for continuous data flow
  - Scatter-gather for a programmable list of arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
  - Independently configured and operated channels
  - Dedicated channels for supported on-chip modules - USB, UART, Ethernet, GP Timer, ADC, EPI, SSI, I<sup>2</sup>S
  - Alternate channel assignments
  - One channel each for receive and transmit path for bidirectional modules
  - Dedicated channel for software-initiated transfers
  - Per-channel configurable bus arbitration scheme
  - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between  $\mu$ DMA controller and the processor core
  - $\mu$ DMA controller access is subordinate to core access
  - RAM striping
  - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment

- Maskable device requests
- Interrupt on transfer completion, with a separate interrupt per channel

## 8.1 Block Diagram

Figure 8-1.  $\mu$ DMA Block Diagram

## 8.2 Functional Description

The  $\mu$ DMA controller is a flexible and highly configurable DMA controller designed to work efficiently with the microcontroller's Cortex-M3 processor core. It supports multiple data sizes and address increment schemes, multiple levels of priority among DMA channels, and several transfer modes to allow for sophisticated programmed data transfers. The DMA controller's usage of the bus is always subordinate to the processor core, and so it never holds up a bus transaction by the processor. Because the  $\mu$ DMA controller is only using otherwise-idle bus cycles, the data transfer bandwidth it provides is essentially free, with no impact on the rest of the system. The bus architecture has been optimized to greatly reduce contention between the processor core and the  $\mu$ DMA controller, thus improving performance. The optimizations include RAM striping and peripheral bus segmentation, which in many cases allows both the processor core and the  $\mu$ DMA controller to access the bus and perform simultaneous data transfers.

Each peripheral function that is supported has a dedicated channel on the  $\mu$ DMA controller that can be configured independently. The  $\mu$ DMA controller implements a unique configuration method using channel control structures that are maintained in system memory by the processor. While simple transfer modes are supported, it is also possible to build up sophisticated "task" lists in memory that allow the  $\mu$ DMA controller to perform arbitrary-sized transfers to and from arbitrary locations as part of a single transfer request. The  $\mu$ DMA controller also supports the use of ping-pong buffering to accommodate constant streaming of data to or from a peripheral.

Each channel also has a configurable arbitration size. The arbitration size is the number of items that are transferred in a burst before the  $\mu$ DMA controller re-arbitrates for channel priority. Using the

arbitration size, it is possible to control exactly how many items are transferred to or from a peripheral each time it makes a DMA service request.

## 8.2.1 Channel Assignments

$\mu$ DMA channels 0-31 are assigned to peripherals according to the following table. The **DMA Channel Alternate Select (DMACHALT)** register (see page 280) can be used to specify the alternate assignment.

**Note:** Channels noted in the table as "Available for software" may be assigned to peripherals in the future. However, they are currently available for software use. Channel 30 is dedicated for software use.

**Table 8-1. DMA Channel Assignments**

DMA Channel	Peripheral Assigned	Alternate Assignment
0	USB Endpoint 1 Receive	UART2 Receive
1	USB Endpoint 1 Transmit	UART2 Transmit
2	USB Endpoint 2 Receive	General-Purpose Timer 3A
3	USB Endpoint 2 Transmit	General-Purpose Timer 3B
4	USB Endpoint 3 Receive	General-Purpose Timer 2A
5	USB Endpoint 3 Transmit	General-Purpose Timer 2B
6	Ethernet Receive	General-Purpose Timer 2A
7	Ethernet Transmit	General-Purpose Timer 2B
8	UART0 Receive	SSI1 Receive
9	UART0 Transmit	SSI1 Transmit
10	SSI0 Receive	UART1 Receive
11	SSI0 Transmit	UART1 Transmit
12	Available for software	UART2 Receive
13	Available for software	UART2 Transmit
14	ADC0 Sample Sequencer 0	General-Purpose Timer 2A
15	ADC0 Sample Sequencer 1	General-Purpose Timer 2B
16	ADC0 Sample Sequencer 2	Available for software
17	ADC0 Sample Sequencer 3	Available for software
18	General-Purpose Timer 0A	General-Purpose Timer 1A
19	General-Purpose Timer 0B	General-Purpose Timer 1B
20	General-Purpose Timer 1A	EPI0 Receive
21	General-Purpose Timer 1B	EPI0 Transmit
22	UART1 Receive	Available for software
23	UART1 Transmit	Available for software
24	SSI1 Receive	ADC1 Sample Sequencer 0
25	SSI1 Transmit	ADC1 Sample Sequencer 1
26	Available for software	ADC1 Sample Sequencer 2
27	Available for software	ADC1 Sample Sequencer 3
28	I <sup>2</sup> S0 Receive	Available for software
29	I <sup>2</sup> S0 Transmit	Available for software
30	Dedicated for software use	
31	Reserved	

## 8.2.2 Priority

The  $\mu$ DMA controller assigns priority to each channel based on the channel number and the priority level bit for the channel. Channel number 0 has the highest priority and as the channel number increases, the priority of a channel decreases. Each channel has a priority level bit to provide two levels of priority: default priority and high priority. If the priority level bit is set, then that channel has higher priority than all other channels at default priority. If multiple channels are set for high priority, then the channel number is used to determine relative priority among all the high priority channels.

The priority bit for a channel can be set using the **DMA Channel Priority Set (DMAPRIOSET)** register and cleared with the **DMA Channel Priority Clear (DMAPRIOCLR)** register.

## 8.2.3 Arbitration Size

When a  $\mu$ DMA channel requests a transfer, the  $\mu$ DMA controller arbitrates among all the channels making a request and services the DMA channel with the highest priority. Once a transfer begins, it continues for a selectable number of transfers before re-arbitrating among the requesting channels again. The arbitration size can be configured for each channel, ranging from 1 to 1024 item transfers. After the  $\mu$ DMA controller transfers the number of items specified by the arbitration size, it then checks among all the channels making a request and services the channel with the highest priority.

If a lower priority DMA channel uses a large arbitration size, the latency for higher priority channels is increased because the  $\mu$ DMA controller completes the lower priority burst before checking for higher priority requests. Therefore, lower priority channels should not use a large arbitration size for best response on high priority channels.

The arbitration size can also be thought of as a burst size. It is the maximum number of items that are transferred at any one time in a burst. Here, the term arbitration refers to determination of DMA channel priority, not arbitration for the bus. When the  $\mu$ DMA controller arbitrates for the bus, the processor always takes priority. Furthermore, the  $\mu$ DMA controller is held off whenever the processor must perform a bus transaction on the same bus, even in the middle of a burst transfer.

## 8.2.4 Request Types

The  $\mu$ DMA controller responds to two types of requests from a peripheral: single or burst. Each peripheral may support either or both types of requests. A single request means that the peripheral is ready to transfer one item, while a burst request means that the peripheral is ready to transfer multiple items.

The  $\mu$ DMA controller responds differently depending on whether the peripheral is making a single request or a burst request. If both are asserted, and the  $\mu$ DMA channel has been set up for a burst transfer, then the burst request takes precedence. See Table 8-2, which shows how each peripheral supports the two request types.

**Table 8-2. Request Type Support**

Peripheral	Single Request Signal	Burst Request Signal
USB TX	None	FIFO TXRDY
USB RX	None	FIFO RXRDY
Ethernet TX	TX FIFO empty	None
Ethernet RX	RX packet received	None
UART TX	TX FIFO Not Full	TX FIFO Level (configurable)
UART RX	RX FIFO Not Empty	RX FIFO Level (configurable)
SSI TX	TX FIFO Not Full	TX FIFO Level (fixed at 4)

Peripheral	Single Request Signal	Burst Request Signal
SSI RX	RX FIFO Not Empty	RX FIFO Level (fixed at 4)
ADC	None	Sequencer IE bit
General-Purpose Timer	Raw interrupt pulse	None
I <sup>2</sup> S TX	None	FIFO service request
I <sup>2</sup> S RX	None	FIFO service request
EPI TX	None	TX FIFO not full
EPI RX	None	RX FIFO not empty

### 8.2.4.1 Single Request

When a single request is detected, and not a burst request, the  $\mu$ DMA controller transfers one item and then stops to wait for another request.

### 8.2.4.2 Burst Request

When a burst request is detected, the  $\mu$ DMA controller transfers the number of items that is the lesser of the arbitration size or the number of items remaining in the transfer. Therefore, the arbitration size should be the same as the number of data items that the peripheral can accommodate when making a burst request. For example, the UART generates a burst request based on the FIFO trigger level. In this case, the arbitration size should be set to the amount of data that the FIFO can transfer when the trigger level is reached.

It may be desirable to use only burst transfers and not allow single transfers. For example, perhaps the nature of the data is such that it only makes sense when transferred together as a single unit rather than one piece at a time. The single request can be disabled by using the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register. By setting the bit for a channel in this register, the  $\mu$ DMA controller only responds to burst requests for that channel.

## 8.2.5 Channel Configuration

The  $\mu$ DMA controller uses an area of system memory to store a set of channel control structures in a table. The control table may have one or two entries for each DMA channel. Each entry in the table structure contains source and destination pointers, transfer size, and transfer mode. The control table can be located anywhere in system memory, but it must be contiguous and aligned on a 1024-byte boundary.

Table 8-3 on page 231 shows the layout in memory of the channel control table. Each channel may have one or two control structures in the control table: a primary control structure and an optional alternate control structure. The table is organized so that all of the primary entries are in the first half of the table, and all the alternate structures are in the second half of the table. The primary entry is used for simple transfer modes where transfers can be reconfigured and restarted after each transfer is complete. In this case, the alternate control structures are not used and therefore only the first half of the table must be allocated in memory; the second half of the control table is not necessary, and that memory can be used for something else. If a more complex transfer mode is used such as ping-pong or scatter-gather, then the alternate control structure is also used and memory space should be allocated for the entire table.

Any unused memory in the control table may be used by the application. This includes the control structures for any channels that are unused by the application as well as the unused control word for each channel.

**Table 8-3. Control Structure Memory Map**

Offset	Channel
0x0	0, Primary
0x10	1, Primary
...	...
0x1F0	31, Primary
0x200	0, Alternate
0x210	1, Alternate
...	...
0x3F0	31, Alternate

Table 8-4 shows an individual control structure entry in the control table. Each entry has a source and destination end pointer. These pointers point to the ending address of the transfer and are inclusive. If the source or destination is non-incrementing (as for a peripheral register), then the pointer should point to the transfer address.

**Table 8-4. Channel Control Structure**

Offset	Description
0x000	Source End Pointer
0x004	Destination End Pointer
0x008	Control Word
0x00C	Unused

The remaining part of the control structure is the control word. The control word contains the following fields:

- Source and destination data sizes
- Source and destination address increment size
- Number of transfers before bus arbitration
- Total number of items to transfer
- Useburst flag
- Transfer mode

The control word and each field are described in detail in “ $\mu$ DMA Channel Control Structure” on page 248. The  $\mu$ DMA controller updates the transfer size and transfer mode fields as the transfer is performed. At the end of a transfer, the transfer size indicates 0, and the transfer mode will indicate "stopped." Because the control word is modified by the  $\mu$ DMA controller, it must be reconfigured before each new transfer. The source and destination end pointers are not modified, so they can be left unchanged if the source or destination addresses remain the same.

Prior to starting a transfer, a  $\mu$ DMA channel must be enabled by setting the appropriate bit in the **DMA Channel Enable Set (DMAENASET)** register. A channel can be disabled by setting the channel bit in the **DMA Channel Enable Clear (DMAENACLR)** register. At the end of a complete DMA transfer, the controller automatically disables the channel.

## 8.2.6 Transfer Modes

The  $\mu$ DMA controller supports several transfer modes. Two of the modes support simple one-time transfers. Several complex modes support a continuous flow of data.

### 8.2.6.1 Stop Mode

While Stop is not actually a transfer mode, it is a valid value for the mode field of the control word. When the mode field has this value, the  $\mu$ DMA controller does not perform any transfers and disables the channel if it is enabled. At the end of a transfer, the  $\mu$ DMA controller updates the control word to set the mode to Stop.

### 8.2.6.2 Basic Mode

In Basic mode, the  $\mu$ DMA controller performs transfers as long as there are more items to transfer, and a transfer request is present. This mode is used with peripherals that assert a DMA request signal whenever the peripheral is ready for a data transfer. Basic mode should not be used in any situation where the request is momentary even though the entire transfer should be completed. For example, a software-initiated transfer creates a momentary request, and in Basic mode, only one item is transferred on a software request.

When all of the items have been transferred using Basic mode, the  $\mu$ DMA controller sets the mode for that channel to Stop.

### 8.2.6.3 Auto Mode

Auto mode is similar to Basic mode, except that once a transfer request is received, the transfer runs to completion, even if the DMA request is removed. This mode is suitable for software-triggered transfers. Generally, Auto mode is not used with a peripheral.

When all the items have been transferred using Auto mode, the  $\mu$ DMA controller sets the mode for that channel to Stop.

### 8.2.6.4 Ping-Pong

Ping-Pong mode is used to support a continuous data flow to or from a peripheral. To use Ping-Pong mode, both the primary and alternate data structures must be implemented. Both structures are set up by the processor for data transfer between memory and a peripheral. The transfer is started using the primary control structure. When the transfer using the primary control structure is complete, the  $\mu$ DMA controller reads the alternate control structure for that channel to continue the transfer. Each time this happens, an interrupt is generated, and the processor can reload the control structure for the just-completed transfer. Data flow can continue indefinitely this way, using the primary and alternate control structures to switch back and forth between buffers as the data flows to or from the peripheral.

Refer to Figure 8-2 for an example showing operation in Ping-Pong mode.

Figure 8-2. Example of Ping-Pong DMA Transaction

### 8.2.6.5 Memory Scatter-Gather

Memory Scatter-Gather mode is a complex mode used when data must be transferred to or from varied locations in memory instead of a set of contiguous locations in a memory buffer. For example, a gather DMA operation could be used to selectively read the payload of several stored packets of a communication protocol and store them together in sequence in a memory buffer.

In Memory Scatter-Gather mode, the primary control structure is used to program the alternate control structure from a table in memory. The table is set up by the processor software and contains a list of control structures, each containing the source and destination end pointers, and the control word for a specific transfer. The mode of each control word must be set to Scatter-Gather mode. Each entry in the table is copied in turn to the alternate structure where it is then executed. The  $\mu$ DMA controller alternates between using the primary control structure to copy the next transfer instruction from the list and then executing the new transfer instruction. The end of the list is marked by programming the control word for the last entry to use Basic transfer mode. Once the last transfer is performed using Basic mode, the  $\mu$ DMA controller stops. A completion interrupt is generated only after the last transfer. It is possible to loop the list by having the last entry copy the primary control structure to point back to the beginning of the list (or to a new list). It is also possible to trigger a set of other channels to perform a transfer, either directly, by programming a write to the software trigger for another channel, or indirectly, by causing a peripheral action that results in a  $\mu$ DMA request.

By programming the  $\mu$ DMA controller using this method, a set of arbitrary transfers can be performed based on a single DMA request.

Refer to Figure 8-3 on page 235 and Figure 8-4 on page 236, which show an example of operation in Memory Scatter-Gather mode. This example shows a *gather* operation, where data in three separate buffers in memory is copied together into one buffer. Figure 8-3 on page 235 shows how the application sets up a  $\mu$ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 8-4 on page 236 shows the sequence as the  $\mu$ DMA controller performs the three sets of copy operations. First, using the primary control structure, the  $\mu$ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the destination buffer. Next, the  $\mu$ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

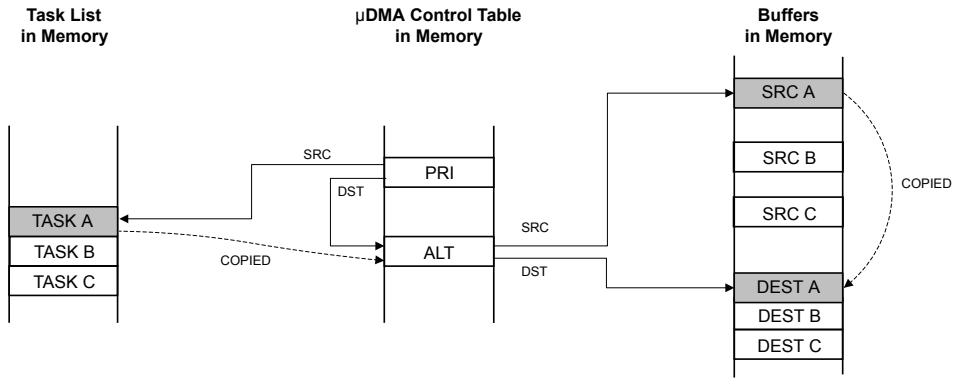

Figure 8-3. Memory Scatter-Gather, Setup and Configuration

## NOTES:

1. Application has a need to copy data items from three separate location in memory into one combined buffer.
2. Application sets up uDMA "task list" in memory, which contains the pointers and control configuration for three uDMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it will be executed by the uDMA controller.

Figure 8-4. Memory Scatter-Gather,  $\mu$ DMA Copy Sequence

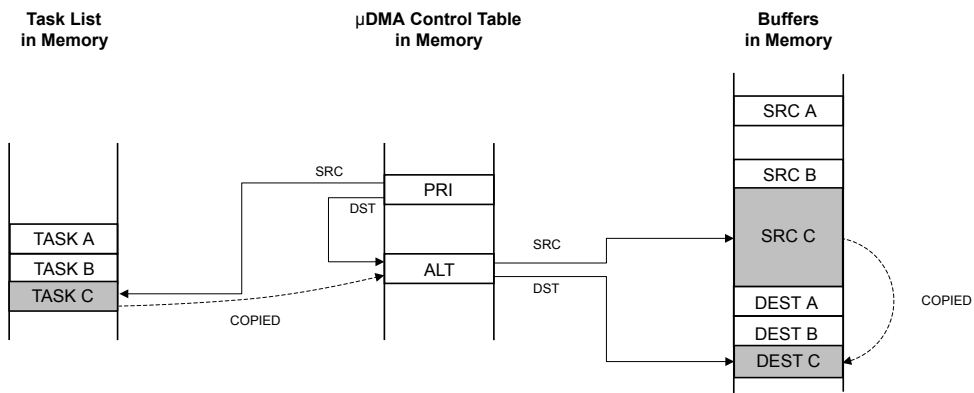

Using the channel's primary control structure, the  $\mu$ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer A to the destination buffer.

Using the channel's primary control structure, the  $\mu$ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer B to the destination buffer.

Using the channel's primary control structure, the  $\mu$ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the  $\mu$ DMA controller copies data from the source buffer C to the destination buffer.

### 8.2.6.6 Peripheral Scatter-Gather

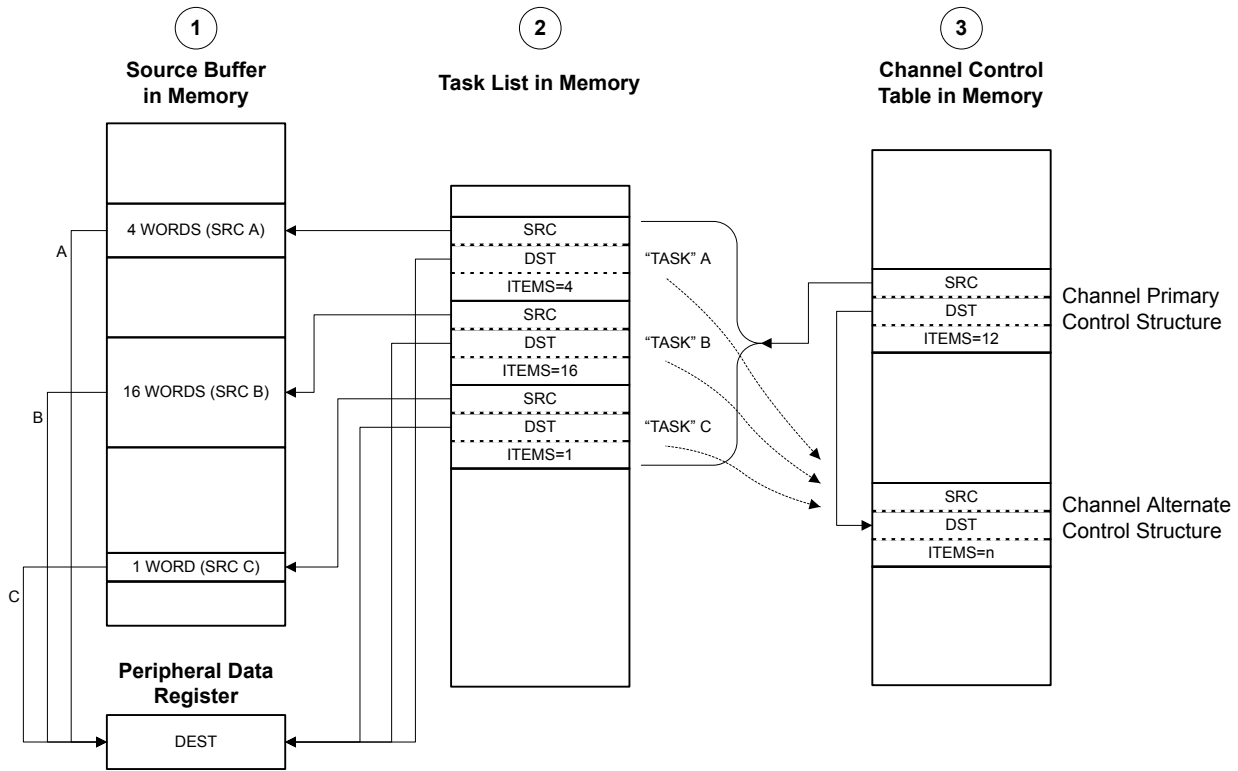

Peripheral Scatter-Gather mode is very similar to Memory Scatter-Gather, except that the transfers are controlled by a peripheral making a DMA request. Upon detecting a DMA request from the peripheral, the  $\mu$ DMA controller uses the primary control structure to copy one entry from the list to the alternate control structure and then performs the transfer. At the end of this transfer, the next transfer is started only if the peripheral again asserts a DMA request. The  $\mu$ DMA controller continues to perform transfers from the list only when the peripheral is making a request, until the last transfer is complete. A completion interrupt is generated only after the last transfer.

By using this method, the  $\mu$ DMA controller can transfer data to or from a peripheral from a set of arbitrary locations whenever the peripheral is ready to transfer data.

Refer to Figure 8-5 on page 238 and Figure 8-6 on page 239, which show an example of operation in Peripheral Scatter-Gather mode. This example shows a gather operation, where data from three separate buffers in memory is copied to a single peripheral data register. Figure 8-5 on page 238 shows how the application sets up a  $\mu$ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 8-6 on page 239 shows the sequence as the  $\mu$ DMA controller performs the three sets of copy operations. First, using the primary control structure, the  $\mu$ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the peripheral data register. Next, the  $\mu$ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

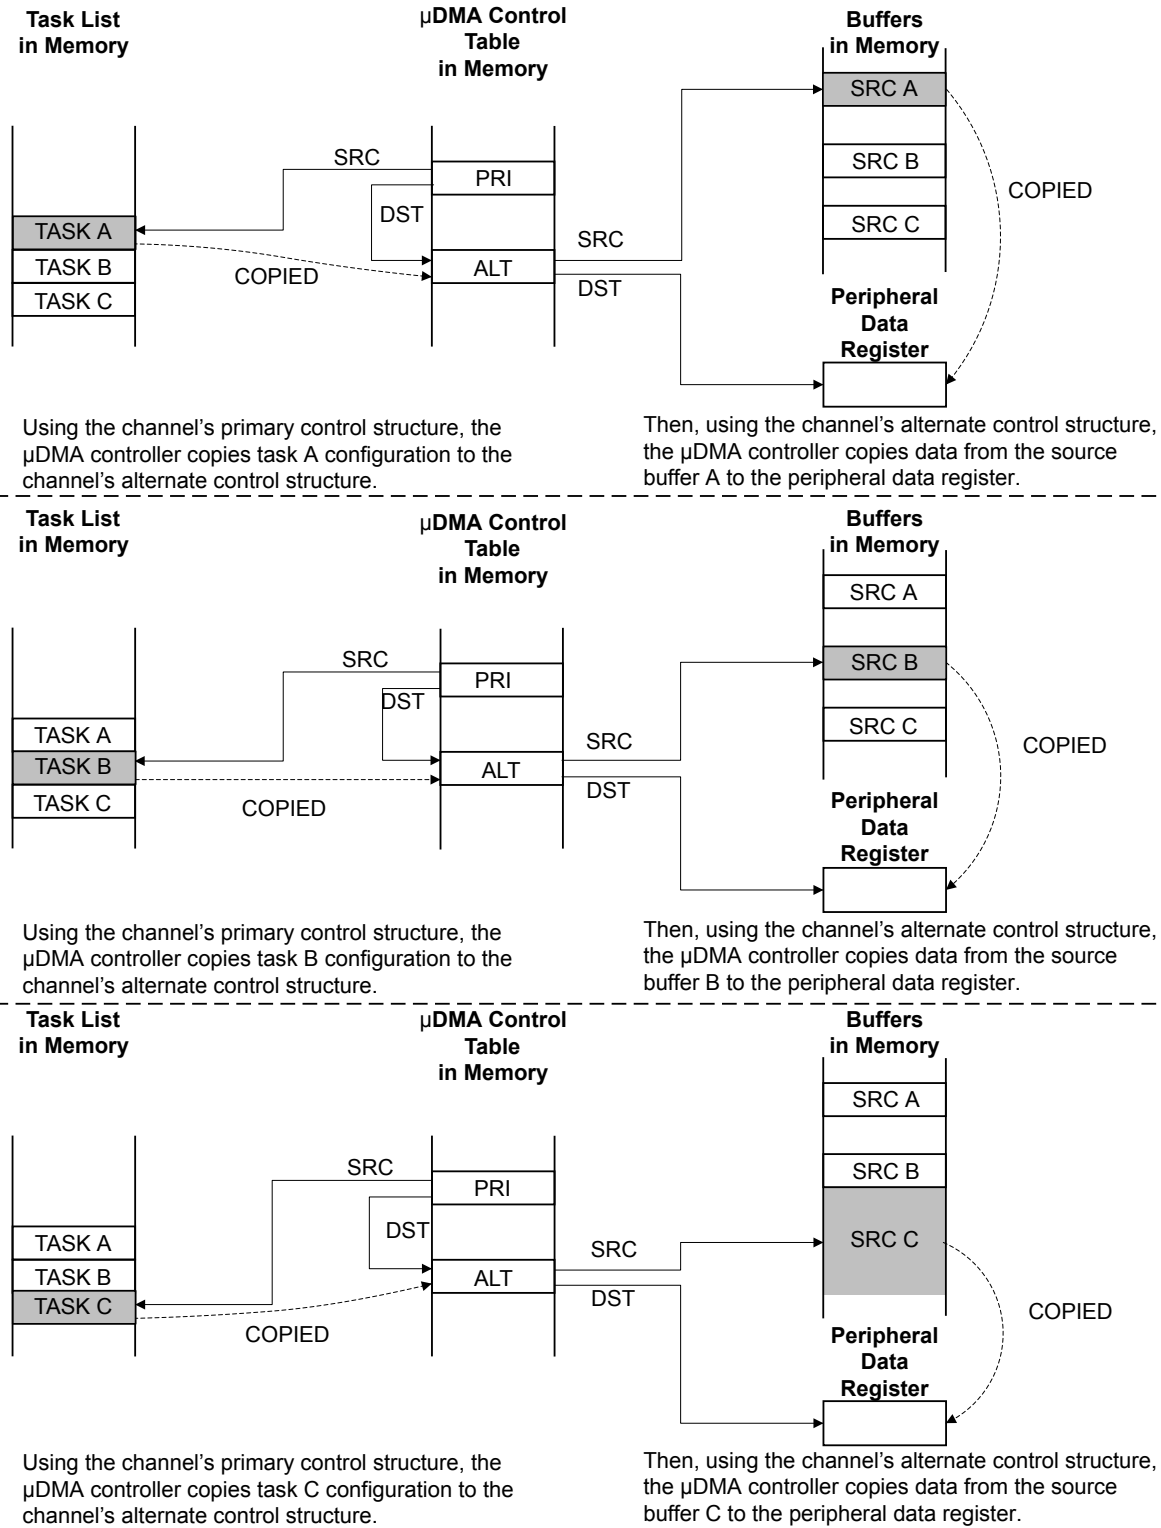

Figure 8-5. Peripheral Scatter-Gather, Setup and Configuration

NOTES:

1. Application has a need to copy data items from three separate location in memory into a peripheral data register.
2. Application sets up  $\mu$ DMA "task list" in memory, which contains the pointers and control configuration for three  $\mu$ DMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it will be executed by the  $\mu$ DMA controller.

Figure 8-6. Peripheral Scatter-Gather,  $\mu$ DMA Copy Sequence

## 8.2.7 Transfer Size and Increment

The  $\mu$ DMA controller supports transfer data sizes of 8, 16, or 32 bits. The source and destination data size must be the same for any given transfer. The source and destination address can be auto-incremented by bytes, half-words, or words, or can be set to no increment. The source and destination address increment values can be set independently, and it is not necessary for the address increment to match the data size as long as the increment is the same or larger than the data size. For example, it is possible to perform a transfer using 8-bit data size, but using an address increment of full words (4 bytes). The data to be transferred must be aligned in memory according to the data size (8, 16, or 32 bits).

Table 8-5 shows the configuration to read from a peripheral that supplies 8-bit data.

**Table 8-5.  $\mu$ DMA Read Example: 8-Bit Peripheral**

Field	Configuration
Source data size	8 bits
Destination data size	8 bits
Source address increment	No increment
Destination address increment	Byte
Source end pointer	Peripheral read FIFO register
Destination end pointer	End of the data buffer in memory

## 8.2.8 Peripheral Interface

Each peripheral that supports  $\mu$ DMA has a DMA single request and/or burst request signal that is asserted when the device is ready to transfer data (see Table 8-2 on page 229). The request signal can be disabled or enabled using the **DMA Channel Request Mask Set (DMAREQMASKSET)** and **DMA Channel Request Mask Clear (DMAREQMASKCLR)** registers. The DMA request signal is disabled, or masked, when the channel request mask bit is set. When the request is not masked, the DMA channel is configured correctly and enabled, and the peripheral asserts the DMA request signal, the  $\mu$ DMA controller begins the transfer.

When a DMA transfer is complete, the  $\mu$ DMA controller asserts a DMA Done signal, which is routed through the interrupt vector of the peripheral. Therefore, if DMA is used to transfer data for a peripheral and interrupts are used, then the interrupt handler for that peripheral must be designed to handle the  $\mu$ DMA transfer completion interrupt. When DMA is enabled for a peripheral, the  $\mu$ DMA controller masks the normal interrupts for a peripheral. Thus, when a large amount of data is transferred using DMA, instead of receiving multiple interrupts from the peripheral as data flows, the processor receives only one interrupt when the transfer is complete.

The interrupt request from the  $\mu$ DMA controller is automatically cleared when the interrupt handler is activated.

## 8.2.9 Software Request

One  $\mu$ DMA channel is dedicated to software-initiated transfers. This channel also has a dedicated interrupt to signal completion of a DMA transfer. A transfer is initiated by software by first configuring and enabling the transfer, and then issuing a software request using the **DMA Channel Software Request (DMASWREQ)** register. For software-based transfers, the Auto transfer mode should be used.

It is possible to initiate a transfer on any channel using the **DMASWREQ** register. If a request is initiated by software using a peripheral DMA channel, then the completion interrupt occurs on the

interrupt vector for the peripheral instead of the software interrupt vector. Any channel may be used for software requests as long as the corresponding peripheral is not using  $\mu$ DMA for data transfer.

## 8.2.10 Interrupts and Errors

When a  $\mu$ DMA channel generates an interrupt, the interrupt status is latched in the **DMA Channel Interrupt Status (DMACHIS)** register (see page 281). This register can be used by the peripheral interrupt handler code to determine if the interrupt was caused by the  $\mu$ DMA channel or something else.

When a DMA transfer is complete, the  $\mu$ DMA controller generates a completion interrupt on the interrupt vector of the peripheral. If the transfer uses the software DMA channel, then the completion interrupt occurs on the dedicated software DMA interrupt vector.

If the  $\mu$ DMA controller encounters a bus or memory protection error as it attempts to perform a data transfer, it disables the DMA channel that caused the error and generates an interrupt on the  $\mu$ DMA Error interrupt vector. The processor can read the **DMA Bus Error Clear (DMAERRCLR)** register to determine if an error is pending. The `ERRCLR` bit is set if an error occurred. The error can be cleared by writing a 1 to the `ERRCLR` bit.

If the peripheral generates an error that causes an interrupt, the interrupt is generated on the interrupt vector for that peripheral. This is the same whether or not  $\mu$ DMA is being used with the peripheral.

Table 8-6 shows the dedicated interrupt assignments for the  $\mu$ DMA controller.

**Table 8-6.  $\mu$ DMA Interrupt Assignments**

Interrupt	Assignment
46	$\mu$ DMA Software Channel Transfer
47	$\mu$ DMA Error

## 8.3 Initialization and Configuration

### 8.3.1 Module Initialization

Before the  $\mu$ DMA controller can be used, it must be enabled in the System Control block and in the peripheral. The location of the channel control structure must also be programmed.

The following steps should be performed one time during system initialization:

1. The  $\mu$ DMA peripheral must be enabled in the System Control block. To do this, set the `UDMA` bit of the System Control **RCGC2** register (page 179).
2. Enable the  $\mu$ DMA controller by setting the `MASTEREN` bit of the **DMA Configuration (DMACFG)** register.
3. Program the location of the channel control table by writing the base address of the table to the **DMA Channel Control Base Pointer (DMACTLBASE)** register. The base address must be aligned on a 1024-byte boundary.

### 8.3.2 Configuring a Memory-to-Memory Transfer

$\mu$ DMA channel 30 is dedicated for software-initiated transfers. However, any channel can be used for software-initiated, memory-to-memory transfer if the associated peripheral is not being used.

### 8.3.2.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Program bit 30 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 30 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 30 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 30 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

### 8.3.2.2 Configure the Channel Control Structure

Now the channel control structure must be configured.

This example transfers 256 words from one memory buffer to another. Channel 30 is used for a software transfer, and the control structure for channel 30 is at offset 0x1E0 of the channel control table. The channel control structure for channel 30 is located at the offsets shown in Table 8-7.

**Table 8-7. Channel Control Structure Offsets for Channel 30**

Offset	Description
Control Table Base + 0x1E0	Channel 30 Source End Pointer
Control Table Base + 0x1E4	Channel 30 Destination End Pointer
Control Table Base + 0x1E8	Channel 30 Control Word

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive).

1. Program the source end pointer at offset 0x1E0 to the address of the source buffer + 0x3FC.
2. Program the destination end pointer at offset 0x1E4 to the address of the destination buffer + 0x3FC.

The control word at offset 0x1E8 must be programmed according to Table 8-8.

**Table 8-8. Channel Control Word Configuration for Memory Transfer Example**

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	2	32-bit destination address increment
DSTSIZE	29:28	2	32-bit destination data size
SRCINC	27:26	2	32-bit source address increment
SRCSIZE	25:24	2	32-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	255	Transfer 256 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	2	Use Auto-request transfer mode

### 8.3.2.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 30 of the **DMA Channel Enable Set (DMAENASET)** register.
2. Issue a transfer request by setting bit 30 of the **DMA Channel Software Request (DMASWREQ)** register.

The DMA transfer begins. If the interrupt is enabled, then the processor is notified by interrupt when the transfer is complete. If needed, the status can be checked by reading bit 30 of the **DMAENASET** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the **XFERMODE** field of the channel control word at offset 0x1E8. This field is automatically cleared at the end of the transfer.

### 8.3.3 Configuring a Peripheral for Simple Transmit

This example configures the  $\mu$ DMA controller to transmit a buffer of data to a peripheral. The peripheral has a transmit FIFO with a trigger level of 4. The example peripheral uses  $\mu$ DMA channel 7.

#### 8.3.3.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 7 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 7 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 7 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 7 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

#### 8.3.3.2 Configure the Channel Control Structure

This example transfers 64 bytes from a memory buffer to the peripheral's transmit FIFO register using  $\mu$ DMA channel 7. The control structure for channel 7 is at offset 0x070 of the channel control table. The channel control structure for channel 7 is located at the offsets shown in Table 8-9.

**Table 8-9. Channel Control Structure Offsets for Channel 7**

Offset	Description
Control Table Base + 0x070	Channel 7 Source End Pointer
Control Table Base + 0x074	Channel 7 Destination End Pointer
Control Table Base + 0x078	Channel 7 Control Word

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register.

1. Program the source end pointer at offset 0x070 to the address of the source buffer + 0x3F.

2. Program the destination end pointer at offset 0x074 to the address of the peripheral's transmit FIFO register.

The control word at offset 0x078 must be programmed according to Table 8-10.

**Table 8-10. Channel Control Word Configuration for Peripheral Transmit Example**

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	3	Destination address does not increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	0	8-bit source address increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	2	Arbitrates after 4 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	1	Use Basic transfer mode

**Note:** In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 4, the arbitration size is set to 4. If the peripheral does make a burst request, then 4 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any space in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst `SET[7]` bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

### 8.3.3.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 7 of the **DMA Channel Enable Set (DMAENASET)** register.

The  $\mu$ DMA controller is now configured for transfer on channel 7. The controller makes transfers to the peripheral whenever the peripheral asserts a DMA request. The transfers continue until the entire buffer of 64 bytes has been transferred. When that happens, the  $\mu$ DMA controller disables the channel and sets the `XFERMODE` field of the channel control word to 0 (Stopped). The status of the transfer can be checked by reading bit 7 of the **DMA Channel Enable Set (DMAENASET)** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the `XFERMODE` field of the channel control word at offset 0x078. This field is automatically cleared at the end of the transfer.

If peripheral interrupts are enabled, then the peripheral interrupt handler receives an interrupt when the entire transfer is complete.

## 8.3.4 Configuring a Peripheral for Ping-Pong Receive

This example configures the  $\mu$ DMA controller to continuously receive 8-bit data from a peripheral into a pair of 64-byte buffers. The peripheral has a receive FIFO with a trigger level of 8. The example peripheral uses  $\mu$ DMA channel 8.

### 8.3.4.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 8 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 8 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 8 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the  $\mu$ DMA controller to respond to single and burst requests.
4. Set bit 8 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the  $\mu$ DMA controller to recognize requests for this channel.

### 8.3.4.2 Configure the Channel Control Structure

This example transfers bytes from the peripheral's receive FIFO register into two memory buffers of 64 bytes each. As data is received, when one buffer is full, the  $\mu$ DMA controller switches to use the other.

To use Ping-Pong buffering, both primary and alternate channel control structures must be used. The primary control structure for channel 8 is at offset 0x080 of the channel control table, and the alternate channel control structure is at offset 0x280. The channel control structures for channel 8 are located at the offsets shown in Table 8-11.

**Table 8-11. Primary and Alternate Channel Control Structure Offsets for Channel 8**

Offset	Description
Control Table Base + 0x080	Channel 8 Primary Source End Pointer
Control Table Base + 0x084	Channel 8 Primary Destination End Pointer
Control Table Base + 0x088	Channel 8 Primary Control Word
Control Table Base + 0x280	Channel 8 Alternate Source End Pointer
Control Table Base + 0x284	Channel 8 Alternate Destination End Pointer
Control Table Base + 0x288	Channel 8 Alternate Control Word

#### **Configure the Source and Destination**

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register. Both the primary and alternate sets of pointers must be configured.

1. Program the primary source end pointer at offset 0x080 to the address of the peripheral's receive buffer.
2. Program the primary destination end pointer at offset 0x084 to the address of ping-pong buffer A + 0x3F.
3. Program the alternate source end pointer at offset 0x280 to the address of the peripheral's receive buffer.
4. Program the alternate destination end pointer at offset 0x284 to the address of ping-pong buffer B + 0x3F.

The primary control word at offset 0x088 and the alternate control word at offset 0x288 must be programmed according to Table 8-10 on page 244. Both control words are initially programmed the same way.

1. Program the primary channel control word at offset 0x088 according to Table 8-12.
2. Program the alternate channel control word at offset 0x288 according to Table 8-12.

**Table 8-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example**

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	0	8-bit destination address increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	3	Source address does not increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	3	Use Ping-Pong transfer mode

**Note:** In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 8, the arbitration size is set to 8. If the peripheral does make a burst request, then 8 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any data in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst `SET[8]` bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

### 8.3.4.3 Configure the Peripheral Interrupt

An interrupt handler should be configured when using  $\mu$ DMA Ping-Pong mode, it is best to use an interrupt handler. However, the Ping-Pong mode can be configured without interrupts by polling. The interrupt handler is triggered after each buffer is complete.

1. Configure and enable an interrupt handler for the peripheral.

### 8.3.4.4 Enable the $\mu$ DMA Channel

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 8 of the **DMA Channel Enable Set (DMAENASET)** register.

### 8.3.4.5 Process Interrupts

The  $\mu$ DMA controller is now configured and enabled for transfer on channel 8. When the peripheral asserts the DMA request signal, the  $\mu$ DMA controller makes transfers into buffer A using the primary channel control structure. When the primary transfer to buffer A is complete, it switches to the alternate channel control structure and makes transfers into buffer B. At the same time, the primary channel control word mode field is configured to indicate Stopped, and an interrupt is

When an interrupt is triggered, the interrupt handler must determine which buffer is complete and process the data or set a flag that the data must be processed by non-interrupt buffer processing code. Then the next buffer transfer must be set up.

In the interrupt handler:

1. Read the primary channel control word at offset 0x088 and check the `XFERMODE` field. If the field is 0, this means buffer A is complete. If buffer A is complete, then:

- a. Process the newly received data in buffer A or signal the buffer processing code that buffer A has data available.
  - b. Reprogram the primary channel control word at offset 0x88 according to Table 8-12 on page 246.
2. Read the alternate channel control word at offset 0x288 and check the `XFERMODE` field. If the field is 0, this means buffer B is complete. If buffer B is complete, then:
    - a. Process the newly received data in buffer B or signal the buffer processing code that buffer B has data available.
    - b. Reprogram the alternate channel control word at offset 0x288 according to Table 8-12 on page 246.

### 8.3.5 Configuring Alternate Channels

Alternate peripherals can be assigned to each  $\mu$ DMA channel using the **DMACHALT** register. Each bit represents a  $\mu$ DMA channel. If the bit is set, then the alternate peripheral is used for the channel.

Refer to Table 8-1 on page 228 for alternate channel assignments.

For example, to use SS11 Receive on channel 8 instead of UART0, set bit 8 of the **DMACHALT** register to 1.

## 8.4 Register Map

Table 8-13 on page 247 lists the  $\mu$ DMA channel control structures and registers. The channel control structure shows the layout of one entry in the channel control table. The channel control table is located in system memory, and the location is determined by the application, that is, the base address is n/a (not applicable). In the table below, the offset for the channel control structures is the offset from the entry in the channel control table. See “Channel Configuration” on page 230 and Table 8-3 on page 231 for a description of how the entries in the channel control table are located in memory. The  $\mu$ DMA register addresses are given as a hexadecimal increment, relative to the  $\mu$ DMA base address of 0x400F.F000. Note that the  $\mu$ DMA module clock must be enabled before the registers can be programmed (see page 179).

**Table 8-13.  $\mu$ DMA Register Map**

## 8.5 $\mu$ DMA Channel Control Structure

The  $\mu$ DMA Channel Control Structure holds the  $\mu$ DMA transfer settings for a  $\mu$ DMA channel. Each channel has two control structures, which are located in a table in system memory. Refer to “Channel Configuration” on page 230 for an explanation of the Channel Control Table and the Channel Control Structure.

The channel control structure is one entry in the channel control table. Each channel has a primary and alternate structure. The primary control structures are located at offsets 0x0, 0x10, 0x20 and so on. The alternate control structures are located at offsets 0x200, 0x210, 0x220, and so on.

## Register 1: DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000

**DMA Channel Source Address End Pointer (DMASRCENDP)** is part of the Channel Control Structure and is used to specify the source address for a  $\mu$ DMA transfer.

**Note:** The offset specified is from the base address of the control structure in system memory, not the  $\mu$ DMA module base address.

### DMA Channel Source Address End Pointer (DMASRCENDP)

Base n/a

Offset 0x000

Type R/W, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDR															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Source Address End Pointer

This field points to the last address of the DMA transfer source (inclusive). If the source address is not incrementing (the **SRCINC** field in the **DMACHCTL** register is 0x3), then this field points at the source location itself (such as a peripheral data register).

## Register 2: DMA Channel Destination Address End Pointer (DMADSTENDP), offset 0x004

**DMA Channel Destination Address End Pointer (DMADSTENDP)** is part of the Channel Control Structure and is used to specify the destination address for a  $\mu$ DMA transfer.

**Note:** The offset specified is from the base address of the control structure in system memory, not the  $\mu$ DMA module base address.

### DMA Channel Destination Address End Pointer (DMADSTENDP)

Base n/a  
Offset 0x004  
Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Destination Address End Pointer

This field points to the last address of the DMA transfer destination (inclusive). If the destination address is not incrementing (the `DSTINC` field in the `DMACHCTL` register is 0x3), then this field points at the destination location itself (such as a peripheral data register).

### Register 3: DMA Channel Control Word (DMACHCTL), offset 0x008

**DMA Channel Control Word (DMACHCTL)** is part of the Channel Control Structure and is used to specify parameters of a  $\mu$ DMA transfer.

**Note:** The offset specified is from the base address of the control structure in system memory, not the  $\mu$ DMA module base address.

#### DMA Channel Control Word (DMACHCTL)

0x0	Stop																					
0x1	Basic																					
0x2	Auto-Request																					
0x3	Ping-Pong																					
0x4	Memory Scatter-Gather																					
0x5	Alternate Memory Scatter-Gather																					
0x6	Peripheral Scatter-Gather																					
0x7	Alternate Peripheral Scatter-Gather																					

**XFERMODE Bit Field Values.**

**Stop**

Channel is stopped or configuration data is invalid. No more transfers can occur.

**Basic**

For each trigger (whether from a peripheral or a software request), the  $\mu$ DMA controller performs the number of transfers specified by the `ARBSIZE` field.

**Auto-Request**

The initial request (software- or peripheral-initiated) is sufficient to complete the entire transfer of `XFERSIZE` items without any further requests.

**Ping-Pong**

This mode uses both the primary and alternate control structures for this channel. When the number of transfers specified by the `XFERSIZE` field have completed for the current control structure (primary or alternate), the  $\mu$ DMA controller switches to the other one. These switches continue until one of the control structures is not set to ping-pong mode. At that point, the  $\mu$ DMA controller stops. An interrupt is generated upon completion of the transfers configured by each control structure. See “Ping-Pong” on page 232.

**Memory Scatter-Gather**

When using this mode, the primary control structure for the channel is configured to allow a list of operations (tasks) to be performed. The source address pointer specifies the start of a table of tasks to be copied to the alternate control structure for this channel. The `XFERMODE` field for the alternate control structure should be configured to 0x5 (Alternate memory scatter-gather) to perform the task. When the task completes, the  $\mu$ DMA switches back to the primary channel control structure, which then copies the next task to the alternate control structure. This process continues until the table of tasks is empty. The last task must have an `XFERMODE` value other than 0x5. Note that for continuous operation, the last task can update the primary channel control structure back to the start of the list or to another list. See “Memory Scatter-Gather” on page 233.

**Alternate Memory Scatter-Gather**

This value must be used in the alternate channel control data structure when the  $\mu$ DMA controller operates in Memory Scatter-Gather mode.

**Peripheral Scatter-Gather**

This value must be used in the primary channel control data structure when the  $\mu$ DMA controller operates in Peripheral Scatter-Gather mode. In this mode, the  $\mu$ DMA controller operates exactly the same as in Memory Scatter-Gather mode, except that instead of performing the number of transfers specified by the `XFERSIZE` field in the alternate control structure at one time, the  $\mu$ DMA controller only performs the number of transfers specified by the `ARBSIZE` field per trigger; see Basic mode for details. See "Peripheral Scatter-Gather" on page 237.

**Alternate Peripheral Scatter-Gather**

This value must be used in the alternate channel control data structure when the  $\mu$ DMA controller operates in Peripheral Scatter-Gather mode.

## 8.6 $\mu$ DMA Register Descriptions

The register addresses given are relative to the  $\mu$ DMA base address of 0x400F.F000.

### Register 4: DMA Status (DMASTAT), offset 0x000

The **DMA Status (DMASTAT)** register returns the status of the  $\mu$ DMA controller. You cannot read this register when the  $\mu$ DMA controller is in the reset state.

#### DMA Status (DMASTAT)

Base 0x400F.F000  
 Offset 0x000  
 Type RO, reset 0x001F.0000

Bit/Field	Name	Type	Reset	Description
31:21	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20:16	DMACHANS	RO	0x1F	Available DMA Channels Minus 1  This field contains a value equal to the number of DMA channels the $\mu$ DMA controller is configured to use, minus one. The value of 0x1F corresponds to 32 DMA channels.
15:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 5: DMA Configuration (DMACFG), offset 0x004

The **DMACFG** register controls the configuration of the  $\mu$ DMA controller.

### DMA Configuration (DMACFG)

Base 0x400F.F000

Offset 0x004

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:1	reserved	WO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	MASTEN	WO	-	Controller Master Enable This bit enables the $\mu$ DMA controller.
				Value Description
				0 Disable
				1 Enable

**Register 6: DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008**

The **DMACTLBASE** register must be configured so that the base pointer points to a location in system memory.

The amount of system memory that must be assigned to the  $\mu$ DMA controller depends on the number of DMA channels used and whether the alternate channel control data structure is used. See “Channel Configuration” on page 230 for details about the Channel Control Table. The base address must be aligned on a 1024-byte boundary. This register cannot be read when the  $\mu$ DMA controller is in the reset state.

**DMA Channel Control Base Pointer (DMACTLBASE)**

Base 0x400F.F000

Offset 0x008

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:10	ADDR	R/W	0x0000.00	Channel Control Base Address  This field contains the pointer to the base address of the channel control table. The base address must be 1024-byte aligned.
9:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

### Register 7: DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C

The **DMAALTBASE** register returns the base address of the alternate channel control data. This register removes the necessity for application software to calculate the base address of the alternate channel control structures. This register cannot be read when the  $\mu$ DMA controller is in the reset state.

#### DMA Alternate Channel Control Base Pointer (DMAALTBASE)

Base 0x400F.F000  
 Offset 0x00C  
 Type RO, reset 0x0000.0200

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RO	0x0000.0200	Alternate Channel Address Pointer  This field provides the base address of the alternate channel control structures.

## Register 8: DMA Channel Wait-on-Request Status (DMAWAITSTAT), offset 0x010

This read-only register indicates that the  $\mu$ DMA channel is waiting on a request. A peripheral can pull this Low to hold off the  $\mu$ DMA from performing a single request until the peripheral is ready for a burst request. The use of this feature is dependent on the design of the peripheral and is used to enhance performance of the  $\mu$ DMA with that peripheral. This register cannot be read when the  $\mu$ DMA controller is in the reset state.

### DMA Channel Wait-on-Request Status (DMAWAITSTAT)

Base 0x400F.F000  
Offset 0x010  
Type RO, reset 0x0000.0000

	WAITREQ[n]															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	WAITREQ[n]	RO	0x0000.0000	Channel [n] Wait Status

These bits provide the channel wait-on-request status. Bit 0 corresponds to channel 0.

#### Value Description

Value	Description
1	The corresponding channel is waiting on a request.
0	The corresponding channel is not waiting on a request.

### Register 9: DMA Channel Software Request (DMASWREQ), offset 0x014

Each bit of the **DMASWREQ** register represents the corresponding  $\mu$ DMA channel. Setting a bit generates a request for the specified  $\mu$ DMA channel.

#### DMA Channel Software Request (DMASWREQ)

Base 0x400F.F000

Offset 0x014

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	SWREQ[n]	WO	-	Channel [n] Software Request These bits generate software requests. Bit 0 corresponds to channel 0.
				Value Description
				1 Generate a software request for the corresponding channel.
				0 No request generated.

**Register 10: DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018**

Each bit of the **DMAUSEBURSTSET** register represents the corresponding  $\mu$ DMA channel. Setting a bit disables the channel's single request input from generating requests, configuring the channel to only accept burst requests. Reading the register returns the status of USEBURST.

When there are fewer items remaining to transfer than the arbitration (burst) size, the  $\mu$ DMA controller automatically clears the corresponding  $SET[n]$  bit, allowing the remaining items to transfer using single requests. A bit should not be set if the corresponding peripheral does not support the burst request model.

Refer to "Request Types" on page 229 for more details about request types.

**Reads****DMA Channel Useburst Set (DMAUSEBURSTSET)**

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	R	0x00	Channel [n] Useburst Status Returns the useburst status of channel [n].
				Value Description
				0 Single and Burst $\mu$ DMA channel [n] responds to single or burst requests.
				1 Burst Only $\mu$ DMA channel [n] responds only to burst requests.

**Writes**

DMA Channel Useburst Set (DMAUSEBURSTSET)

Base 0x400F.F000  
 Offset 0x018  
 Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	W	0x00	Channel [n] Useburst Set
				Sets useburst bit on channel [n]. Use the <b>DMAUSEBURSTCLR</b> register to clear bit [n].
				Value Description
				0 No Effect
				1 Burst Only
				$\mu$ DMA channel [n] responds only to burst requests.

**Register 11: DMA Channel Useburst Clear (DMAUSEBURSTCLR), offset 0x01C**

Each bit of the **DMAUSEBURSTCLR** register represents the corresponding DMA channel. Writing a 1 enables `dma_sreq[n]` to generate requests.

## DMA Channel Useburst Clear (DMAUSEBURSTCLR)

Base 0x400F.F000

Offset 0x01C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	CLR[n]	WO	-	Channel [n] Useburst Clear Clears useburst bit on channel [n].
				Value Description
				0 No Effect
				Use the <b>DMAUSEBURSTSET</b> to set bit [n] to 1.
				1 Single and Burst
				DMA channel [n] responds to single and burst requests.

## Register 12: DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020

Each bit of the **DMAREQMASKSET** register represents the corresponding DMA channel. Writing a 1 disables DMA requests for the channel. Reading the register returns the request mask status. When a  $\mu$ DMA channel's request is masked, that means the peripheral can no longer request  $\mu$ DMA transfers. The channel can then be used for software-initiated transfers.

## 9 General-Purpose Input/Outputs (GPIOs)

The GPIO module is composed of nine physical GPIO blocks, each corresponding to an individual GPIO port (Port A, Port B, Port C, Port D, Port E, Port F, Port G, Port H, Port J). The GPIO module supports 0-65 programmable input/output pins, depending on the peripherals being used.

The GPIO module has the following features:

- 0-65 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 5-V-tolerant input/outputs
- Fast toggle capable of a change every two clock cycles
- Two means of port access: either Advanced Host Bus (AHB) with better back-to-back access performance, or the legacy Advanced Peripheral Bus (APB) for backwards-compatibility with existing code
- Programmable control for GPIO interrupts
  - Interrupt generation masking
  - Edge-triggered on rising, falling, or both
  - Level-sensitive on High or Low values
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
  - Weak pull-up or pull-down resistors
  - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can be configured with an 18-mA pad drive for high-current applications
  - Slew rate control for the 8-mA drive
  - Open drain enables
  - Digital input enables

### 9.1 Functional Description

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**) with the exception of the pins shown in Table 9-1. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 9-1. GPIO Pins With Non-Zero Reset Values**

GPIO Pins	Default State	GPIOAFSEL	GIODEN	GPIOPDR	GPIOPUR	GPIOCTL
PA[1:0]	UART0	1	1	0	0	0x1
PA[5:2]	SSI0	1	1	0	0	0x1
PB[3:2]	I <sup>2</sup> C0	1	1	0	0	0x1
PC[3:0]	JTAG	1	1	0	1	0x3

Each GPIO port is a separate hardware instantiation of the same physical block (see Figure 9-1 on page 292 and Figure 9-2 on page 293). The LM3S9792 microcontroller contains nine ports and thus nine of these physical GPIO blocks. Some GPIO pins can function as I/O signals for the on-chip peripheral modules. For information on which GPIO pins are used for alternate hardware functions, refer to Table 25-5 on page 990.

**Figure 9-1. Digital I/O Pads**

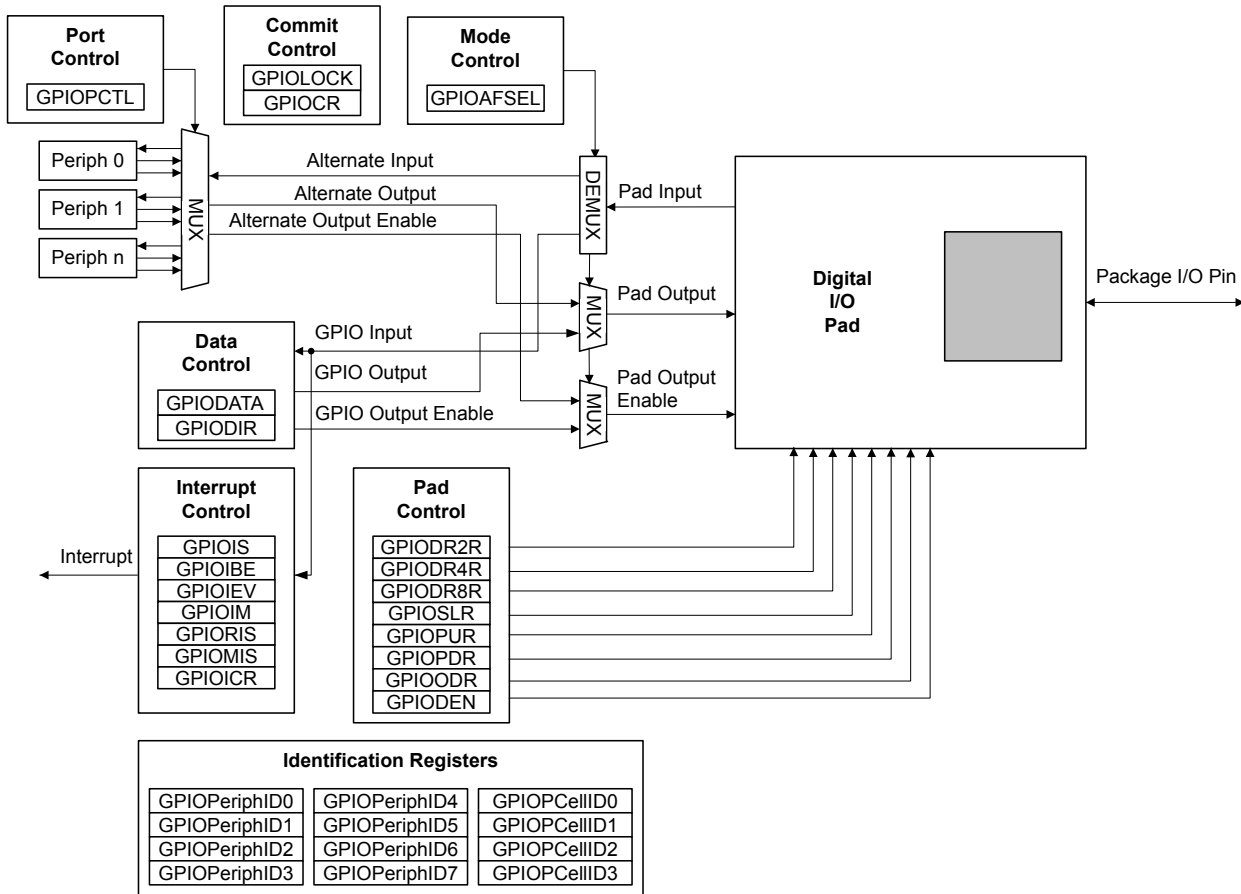

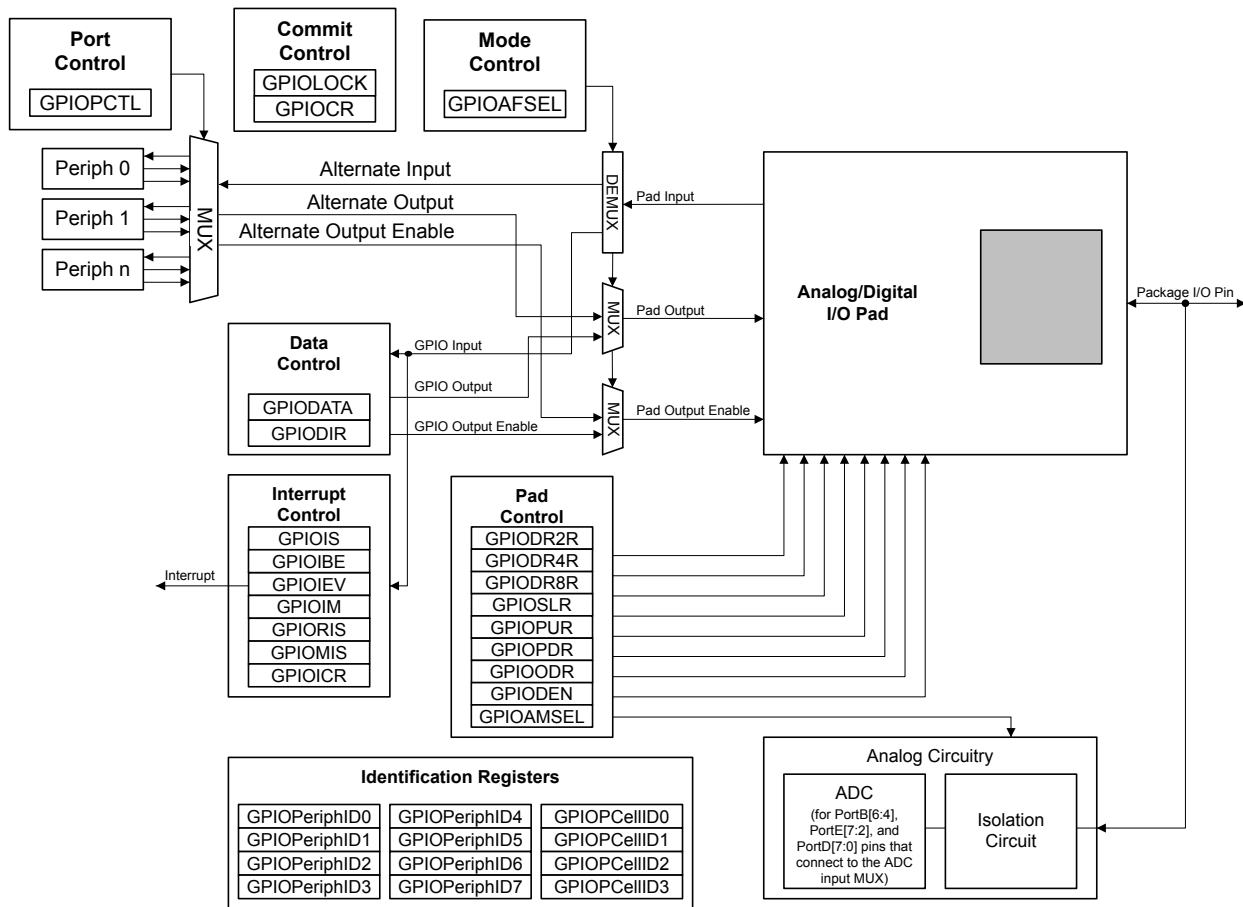

Figure 9-2. Analog/Digital I/O Pads

### 9.1.1 Data Control

The data control registers allow software to configure the operational modes of the GPIOs. The data direction register configures the GPIO as an input or an output while the data register either captures incoming data or drives it out to the pads.

**Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.**

#### 9.1.1.1 Data Direction Operation

The **GPIO Direction (GPIODIR)** register (see page 302) is used to configure each individual pin as an input or output. When the data direction bit is cleared, the GPIO is configured as an input, and the corresponding data register bit captures and stores the value on the GPIO port. When the data direction bit is set, the GPIO is configured as an output, and the corresponding data register bit is driven out on the GPIO port.

### 9.1.1.2 Data Register Operation

To aid in the efficiency of software, the GPIO ports allow for the modification of individual bits in the **GPIO Data (GPIODATA)** register (see page 301) by using bits [9:2] of the address bus as a mask. In this manner, software drivers can modify individual GPIO pins in a single instruction without affecting the state of the other pins. This method is more efficient than the conventional method of performing a read-modify-write operation to set or clear an individual GPIO pin. To implement this feature, the **GPIODATA** register covers 256 locations in the memory map.

During a write, if the address bit associated with that data bit is set, the value of the **GPIODATA** register is altered. If the address bit is cleared, the data bit is left unchanged.

For example, writing a value of 0xEB to the address GPIODATA + 0x098 has the results shown in Figure 9-3, where u indicates that data is unchanged by the write.

**Figure 9-3. GPIODATA Write Example**

During a read, if the address bit associated with the data bit is set, the value is read. If the address bit associated with the data bit is cleared, the data bit is read as a zero, regardless of its actual value. For example, reading address GPIODATA + 0x0C4 yields as shown in Figure 9-4.

**Figure 9-4. GPIODATA Read Example**

### 9.1.2 Interrupt Control

The interrupt capabilities of each GPIO port are controlled by a set of seven registers. These registers are used to select the source of the interrupt, its polarity, and the edge properties. When one or more GPIO inputs cause an interrupt, a single interrupt output is sent to the interrupt controller for the entire GPIO port. For edge-triggered interrupts, software must clear the interrupt to enable any further interrupts. For a level-sensitive interrupt, the external source must hold the level constant for the interrupt to be recognized by the controller.

Three registers define the edge or sense that causes interrupts:

- **GPIO Interrupt Sense (GPIOIS)** register (see page 303)

- **GPIO Interrupt Both Edges (GPIOIBE)** register (see page 304)
- **GPIO Interrupt Event (GPIOIEV)** register (see page 305)

Interrupts are enabled/disabled via the **GPIO Interrupt Mask (GPIOIM)** register (see page 306).

When an interrupt condition occurs, the state of the interrupt signal can be viewed in two locations: the **GPIO Raw Interrupt Status (GPIORIS)** and **GPIO Masked Interrupt Status (GPIOMIS)** registers (see page 307 and page 308). As the name implies, the **GPIOMIS** register only shows interrupt conditions that are allowed to be passed to the interrupt controller. The **GPIORIS** register indicates that a GPIO pin meets the conditions for an interrupt, but has not necessarily been sent to the interrupt controller.

In addition to providing GPIO functionality,  $PB4$  can also be used as an external trigger for the ADC. If  $PB4$  is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), an interrupt for Port B is generated, and an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated. See page 477.

If no other Port B pins are being used to generate interrupts, the ARM Integrated Nested Vectored Interrupt Controller (NVIC) Interrupt Set Enable (SETENA) register can disable the Port B interrupts, and the ADC interrupt can be used to read back the converted data. Otherwise, the Port B interrupt handler must ignore and clear interrupts on  $PB4$  and wait for the ADC interrupt, or the ADC interrupt must be disabled in the SETENA register and the Port B interrupt handler must poll the ADC registers until the conversion is completed. See the *ARM® Cortex™-M3 Technical Reference Manual* for more information.

Interrupts are cleared by writing a 1 to the appropriate bit of the **GPIO Interrupt Clear (GPIOICR)** register (see page 310).

When programming the interrupt control registers (**GPIOIS**, **GPIOIBE**, or **GPIOIEV**), the interrupts should be masked (**GPIOIM** cleared). Writing any value to an interrupt control register can generate a spurious interrupt if the corresponding bits are enabled.

### 9.1.3 Mode Control

The GPIO pins can be controlled by either software or hardware. Software control is the default for most signals and corresponds to the GPIO mode, where the **GPIO DATA** register is used to read or write the corresponding pins. When hardware control is enabled via the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 311), the pin state is controlled by its alternate function (that is, the peripheral).

Further pin muxing options are provided through the **GPIO Port Control (GPIOCTL)** register which selects one of several peripheral functions for each GPIO. For information on the configuration options, refer to Table 25-5 on page 990.

**Note:** If any pin is to be used as an ADC input, the appropriate bit in the **GPIOAMSEL** register must be set to disable the analog isolation circuit.

### 9.1.4 Commit Control

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the **NMI** pin ( $PB7$ ) and the four **JTAG/SWD** pins ( $PC[3:0]$ ). Writes to protected bits of the **GPIOAFSEL** register, **GPIOPUR** register, **GPIO Pull-Down Select (GPIOPDR)** register (see page 319), and **GPIODEN** register are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 323) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 324) have been set.

### 9.1.5 Pad Control

The pad control registers allow software to configure the GPIO pads based on the application requirements. The pad control registers include the **GPIO2R**, **GPIO4R**, **GPIO8R**, **GPIOODR**, **GPIOPUR**, **GPIOPDR**, **GPIOSLR**, and **GIODEN** registers. These registers control drive strength, open-drain configuration, pull-up and pull-down resistors, slew-rate control and digital input enable for each GPIO.

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the  $V_{OL}$  value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

### 9.1.6 Identification

The identification registers configured at reset allow software to detect and identify the module as a GPIO block. The identification registers include the **GPIOPeriphID0-GIOPeriphID7** registers as well as the **GPIOCellID0-GIOPCellID3** registers.

## 9.2 Initialization and Configuration

The GPIO modules may be accessed via two different memory apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous Stellaris® parts. The other aperture, the Advanced Host Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus. These apertures are mutually exclusive. The aperture enabled for a given GPIO port is controlled by the appropriate bit in the **GPIOHBCTL** register (see page 119).

To use the pins in a particular GPIO port, the clock for the port must be enabled by setting the appropriate GPIO Port bit field ( $GPIO_n$ ) in the **RCGC2** register (see page 179).

On reset, all GPIO pins are configured out of reset to be undriven (tristate): **GPIOAFSEL=0**, **GIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**, except for the pins shown in Table 9-1 on page 292. Table 9-2 on page 296 shows all possible configurations of the GPIO pads and the control register settings required to achieve them. Table 9-3 on page 297 shows how a rising edge interrupt is configured for pin 2 of a GPIO port.

**Table 9-2. GPIO Pad Configuration Examples**

Configuration	GPIO Register Bit Value <sup>a</sup>									
	AFSEL	DIR	ODR	DEN	PUR	PDR	DR2R	DR4R	DR8R	SLR

a. X=Ignored (don't care bit)

## 9.3 Register Map

Table 9-5 on page 299 lists the GPIO registers. Each GPIO port can be accessed through one of two bus apertures. The legacy aperture, the Advanced Peripheral Bus (APB), is backwards-compatible with previous Stellaris<sup>®</sup> parts. The other aperture, the Advanced Host Bus (AHB), offers the same register map but provides better back-to-back access performance than the APB bus.

**Important:** The GPIO registers in this chapter are duplicated in each GPIO block; however, depending on the block, all eight bits may not be connected to a GPIO pad. In those cases, writing to unconnected bits has no effect, and reading unconnected bits returns no meaningful data.

The offset listed is a hexadecimal increment to the register's address, relative to that GPIO port's base address:

- GPIO Port A (APB): 0x4000.4000
- GPIO Port A (AHB): 0x4005.8000
- GPIO Port B (APB): 0x4000.5000
- GPIO Port B (AHB): 0x4005.9000
- GPIO Port C (APB): 0x4000.6000
- GPIO Port C (AHB): 0x4005.A000
- GPIO Port D (APB): 0x4000.7000
- GPIO Port D (AHB): 0x4005.B000
- GPIO Port E (APB): 0x4002.4000
- GPIO Port E (AHB): 0x4005.C000
- GPIO Port F (APB): 0x4002.5000
- GPIO Port F (AHB): 0x4005.D000
- GPIO Port G (APB): 0x4002.6000
- GPIO Port G (AHB): 0x4005.E000
- GPIO Port H (APB): 0x4002.7000
- GPIO Port H (AHB): 0x4005.F000
- GPIO Port J (APB): 0x4003.D000
- GPIO Port J (AHB): 0x4006.0000

Note that each GPIO module clock must be enabled before the registers can be programmed (see page 179).

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, and **GPIOPUR**=0) with the exception of the pins shown in Table 9-1. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 9-4. GPIO Pins With Non-Zero Reset Values**

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PA[1:0]	UART0	1	1	0	0	0x1
PA[5:2]	SSI0	1	1	0	0	0x1
PB[3:2]	I <sup>2</sup> C0	1	1	0	0	0x1
PC[3:0]	JTAG	1	1	0	1	0x3

**Note:** The default register type for the **GPIOCR** register is RO for all GPIO pins with the exception of the **NMI** pin and the four JTAG/SWD pins (**PB7** and **PC[3:0]**). These five pins are currently the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the **NMI** pin and the four JTAG/SWD pins (**PB7** and **PC[3:0]**). To ensure that the JTAG port is not accidentally programmed as a GPIO, these four pins default to non-committable. To ensure that the **NMI** pin is not accidentally programmed as the non-maskable interrupt pin, it defaults to non-committable. Because of this, the default reset value of **GPIOCR** for GPIO Port B is 0x0000.007F while the default reset value of **GPIOCR** for Port C is 0x0000.00F0.

Table 9-5. GPIO Register Map

Offset	Name	Type	Reset	Description	See page

## 9.4 Register Descriptions

The remainder of this section lists and describes the GPIO registers, in numerical order by address offset.

### Register 1: GPIO Data (GPIODATA), offset 0x000

The **GPIODATA** register is the data register. In software control mode, values written in the **GPIODATA** register are transferred onto the GPIO port pins if the respective pins have been configured as outputs through the **GPIO Direction (GPIODIR)** register (see page 302).

In order to write to **GPIODATA**, the corresponding bits in the mask, resulting from the address bus bits [9:2], must be set. Otherwise, the bit values remain unchanged by the write.

Similarly, the values read from this register are determined for each bit by the mask bit derived from the address used to access the data register, bits [9:2]. Bits that are set in the address mask cause the corresponding bits in **GPIODATA** to be read, and bits that are clear in the address mask cause the corresponding bits in **GPIODATA** to be read as 0, regardless of their value.

A read from **GPIODATA** returns the last bit value written if the respective pins are configured as outputs, or it returns the value on the corresponding input pin when these are configured as inputs. All bits are cleared by a reset.

#### GPIO Data (GPIODATA)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	R/W	0x00	GPIO Data

This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and written to the registers are masked by the eight address lines [9:2]. Reads from this register return its current state. Writes to this register only affect bits that are not masked by ADDR[9:2] and are configured as outputs. See “Data Register Operation” on page 294 for examples of reads and writes.

### Register 2: GPIO Direction (GPIODIR), offset 0x400

The **GPIODIR** register is the data direction register. Setting a bit in the **GPIODIR** register configures the corresponding pin to be an output, while clearing a bit configures the corresponding pin to be an input. All bits are cleared by a reset, meaning all GPIO pins are inputs by default.

#### GPIO Direction (GPIODIR)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x400  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DIR	R/W	0x00	GPIO Data Direction

Value Description

- 0 Corresponding pin is an input.
- 1 Corresponding pins is an output.

### Register 3: GPIO Interrupt Sense (GPIOIS), offset 0x404

The **GPIOIS** register is the interrupt sense register. Setting a bit in the **GPIOIS** register configures the corresponding pin to detect levels, while clearing a bit configures the corresponding pin to detect edges. All bits are cleared by a reset.

#### GPIO Interrupt Sense (GPIOIS)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000

31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IS	R/W	0x00	GPIO Interrupt Sense

#### Value Description

- |   |   |
|---|---|
| 0 | The edge on the corresponding pin is detected (edge-sensitive).   |
| 1 | The level on the corresponding pin is detected (level-sensitive). |

### Register 4: GPIO Interrupt Both Edges (GPIOIBE), offset 0x408

The **GPIOIBE** register allows both edges to cause interrupts. When the corresponding bit in the **GPIO Interrupt Sense (GPIOIS)** register (see page 303) is set to detect edges, setting a bit in the **GPIOIBE** register configures the corresponding pin to detect both rising and falling edges, regardless of the corresponding bit in the **GPIO Interrupt Event (GPIOIEV)** register (see page 305). Clearing a bit configures the pin to be controlled by the **GPIOIEV** register. All bits are cleared by a reset.

#### GPIO Interrupt Both Edges (GPIOIBE)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x408  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IBE	R/W	0x00	GPIO Interrupt Both Edges

**Value Description**

- 0 Interrupt generation is controlled by the **GPIO Interrupt Event (GPIOIEV)** register (see page 305).
- 1 Both edges on the corresponding pin trigger an interrupt.

### Register 5: GPIO Interrupt Event (GPIOIEV), offset 0x40C

The **GPIOIEV** register is the interrupt event register. Setting a bit in the **GPIOIEV** register configures the corresponding pin to detect rising edges or high levels, depending on the corresponding bit value in the **GPIO Interrupt Sense (GPIOIS)** register (see page 303). Clearing a bit configures the pin to detect falling edges or low levels, depending on the corresponding bit value in the **GPIOIS** register. All bits are cleared by a reset.

#### GPIO Interrupt Event (GPIOIEV)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x40C  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IEV	R/W	0x00	GPIO Interrupt Event

Value	Description
0	A falling edge or a Low level on the corresponding pin triggers an interrupt.
1	A rising edge or a High level on the corresponding pin triggers an interrupt.

### Register 6: GPIO Interrupt Mask (GPIOIM), offset 0x410

The **GPIOIM** register is the interrupt mask register. Setting a bit in the **GPIOIM** register allows interrupts that are generated by the corresponding pin to be sent to the interrupt controller on the combined interrupt signal. Clearing a bit prevents an interrupt on the corresponding pin from being sent to the interrupt controller. All bits are cleared by a reset.

#### GPIO Interrupt Mask (GPIOIM)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x410  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IME	R/W	0x00	GPIO Interrupt Mask Enable

Value	Description
0	The interrupt from the corresponding pin is masked.
1	The interrupt from the corresponding pin is sent to the interrupt controller.

### Register 7: GPIO Raw Interrupt Status (GPIORIS), offset 0x414

The **GPIORIS** register is the raw interrupt status register. A bit in this register is set when an interrupt condition occurs on the corresponding GPIO pin. If the corresponding bit in the **GPIO Interrupt Mask (GPIOIM)** register (see page 306) is set, the interrupt is sent to the interrupt controller. Bits read as zero indicate that corresponding input pins have not initiated an interrupt. A bit in this register can be cleared by writing a 1 to the corresponding bit in the **GPIO Interrupt Clear (GPIOICR)** register.

#### GPIO Raw Interrupt Status (GPIORIS)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x414  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	RIS	RO	0x00	GPIO Interrupt Raw Status

Value	Description
1	An interrupt condition has occurred on the corresponding pin.
0	An interrupt condition has not occurred on the corresponding pin.

A bit is cleared by writing a 1 to the corresponding bit in the **GPIOICR** register.

### Register 8: GPIO Masked Interrupt Status (GPIOMIS), offset 0x418

The **GPIOMIS** register is the masked interrupt status register. If a bit is set in this register, the corresponding interrupt has triggered an interrupt to the interrupt controller. If a bit is clear, either no interrupt has been generated, or the interrupt is masked.

In addition to providing GPIO functionality, **PB4** can also be used as an external trigger for the ADC. If **PB4** is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), an interrupt for Port B is generated, and an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated. See page 477.

If no other Port B pins are being used to generate interrupts, the ARM Integrated Nested Vectored Interrupt Controller (NVIC) Interrupt Set Enable (SETNA) register can disable the Port B interrupts, and the ADC interrupt can be used to read back the converted data. Otherwise, the Port B interrupt handler must ignore and clear interrupts on PB4 and wait for the ADC interrupt, or the ADC interrupt must be disabled in the SETNA register and the Port B interrupt handler must poll the ADC registers until the conversion is completed. See the *ARM® Cortex™-M3 Technical Reference Manual* for more information.

**GPIOMIS** is the state of the interrupt after masking.

#### GPIO Masked Interrupt Status (GPIOMIS)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x418  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

---

Bit/Field	Name	Type	Reset	Description
7:0	MIS	RO	0x00	GPIO Masked Interrupt Status
				Value Description
				1 An interrupt condition on the corresponding pin has triggered an interrupt to the interrupt controller.
				0 An interrupt condition on the corresponding pin is masked or has not occurred.
				A bit is cleared by writing a 1 to the corresponding bit in the <b>GPIOICR</b> register.

### Register 9: GPIO Interrupt Clear (GPIOICR), offset 0x41C

The **GPIOICR** register is the interrupt clear register. Writing a 1 to a bit in this register clears the corresponding interrupt bit in the **GPIOIRIS** and **GPIOMIS** registers. Writing a 0 has no effect.

#### GPIO Interrupt Clear (GPIOICR)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x41C  
 Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IC	W1C	0x00	GPIO Interrupt Clear

Value	Description
1	The corresponding interrupt is cleared.
0	The corresponding interrupt is unaffected.

## Register 10: GPIO Alternate Function Select (GPIOAFSEL), offset 0x420

The **GPIOAFSEL** register is the mode control select register. If a bit is clear, the pin is used as a GPIO and is controlled by the GPIO registers. Setting a bit in this register configures the corresponding GPIO line to be controlled by an associated peripheral. Several possible peripheral functions are multiplexed on each GPIO. The **GPIO Port Control (GPIOPCTL)** register is used to select one of the possible functions. Table 25-5 on page 990 details which functions are muxed on each GPIO pin. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 9-1.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, and **GPIOPUR**=0) with the exception of the pins shown in Table 9-1. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 9-6. GPIO Pins With Non-Zero Reset Values**

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PA[1:0]	UART0	1	1	0	0	0x1
PA[5:2]	SSI0	1	1	0	0	0x1
PB[3:2]	I <sup>2</sup> C0	1	1	0	0	0x1
PC[3:0]	JTAG	1	1	0	1	0x3

**Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris<sup>®</sup> microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.**

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the **NMI** pin (**PB7**) and the four JTAG/SWD pins (**PC[3:0]**). Writes to protected bits of the **GPIOAFSEL** register, **GPIOPUR** register, **GPIO Pull-Down Select (GPIOPDR)** register (see page 319), and **GPIODEN** register are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 323) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 324) have been set.

When using the I<sup>2</sup>C module, in addition to setting the **GPIOAFSEL** register bits for the I<sup>2</sup>C clock and data pins, the pins should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register (see examples in “Initialization and Configuration” on page 296).

GPIO Alternate Function Select (GPIOAFSEL)

7:0	AFSEL	R/W	-	GPIO Alternate Function Select

Value Description

- 0 The associated pin functions as a GPIO and is controlled by the GPIO registers.
- 1 The associated pin functions as a peripheral signal and is controlled by the alternate hardware function.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 9-1 on page 292.

## Register 11: GPIO 2-mA Drive Select (GPIODR2R), offset 0x500

The **GPIODR2R** register is the 2-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV2** bit for a GPIO signal, the corresponding **DRV4** bit in the **GPIODR4R** register and **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware. By default, all GPIO pins have 2-mA drive.

7:0	DRV2	R/W	0xFF	Output Pad 2-mA Drive Enable

#### Value Description

- |   |  |
|---|--|
| 1 | The corresponding GPIO pin has 2-mA drive.   |
| 0 | The drive for the corresponding GPIO pin is controlled by the <b>GPIODR4R</b> or <b>GPIODR8R</b> register. |

Setting a bit in either the **GPIODR4** register or the **GPIODR8** register clears the corresponding 2-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

### Register 12: GPIO 4-mA Drive Select (GPIODR4R), offset 0x504

The **GPIODR4R** register is the 4-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV4** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware.

#### GPIO 4-mA Drive Select (GPIODR4R)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000

 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x504

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV4	R/W	0x00	Output Pad 4-mA Drive Enable

**Value Description**

- 1 The corresponding GPIO pin has 4-mA drive.
- 0 The drive for the corresponding GPIO pin is controlled by the **GPIODR2R** or **GPIODR8R** register.

Setting a bit in either the **GPIODR2** register or the **GPIODR8** register clears the corresponding 4-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

## Register 13: GPIO 8-mA Drive Select (GPIODR8R), offset 0x508

The **GPIODR8R** register is the 8-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV8** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and **DRV4** bit in the **GPIODR4R** register are automatically cleared by hardware. The 8-mA setting is also used for high-current operation.

**Note:** There is no configuration difference between 8-mA and high-current operation. The additional current capacity results from a shift in the  $V_{OH}/V_{OL}$  levels. See “Recommended DC Operating Conditions” on page 993 for further information.

### GPIO 8-mA Drive Select (GPIODR8R)

7:0	DRV8	R/W	0x00	Output Pad 8-mA Drive Enable

#### Value Description

- 1 The corresponding GPIO pin has 8-mA drive.
- 0 The drive for the corresponding GPIO pin is controlled by the **GPIODR2R** or **GPIODR4R** register.

Setting a bit in either the **GPIODR2** register or the **GPIODR4** register clears the corresponding 8-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

### Register 14: GPIO Open Drain Select (GPIOODR), offset 0x50C

The **GPIOODR** register is the open drain control register. Setting a bit in this register enables the open-drain configuration of the corresponding GPIO pad. When open-drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Input Enable (GPIODEN)** register (see page 321). Corresponding bits in the drive strength and slew rate control registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired rise and fall times. The GPIO acts as an open-drain input if the corresponding bit in the **GPIODIR** register is cleared; and as an open-drain output when it is set.

When using the I<sup>2</sup>C module, in addition to configuring the pin to open drain, the **GPIO Alternate Function Select (GPIOAFSEL)** register bits for the I<sup>2</sup>C clock and data pins should be set (see examples in “Initialization and Configuration” on page 296).

#### GPIO Open Drain Select (GPIOODR)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (APB) base: 0x4000.6000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (APB) base: 0x4000.7000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (APB) base: 0x4002.4000

 GPIO Port F (APB) base: 0x4002.5000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (APB) base: 0x4002.6000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x50C  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	ODE	R/W	0x00	Output Pad Open Drain Enable

Value	Description
1	The corresponding pin is configured as open drain.
0	The corresponding pin is not configured as open drain.

### Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510

The **GPIOPUR** register is the pull-up control register. When a bit is set, a weak pull-up resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 319). Write access to this register is protected with the **GPIOCR** register. Bits in **GPIOCR** that are cleared prevent writes to the equivalent bit in this register.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, and **GPIOPUR**=0) with the exception of the pins shown in Table 9-1. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

Table 9-7. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PA[1:0]	UART0	1	1	0	0	0x1
PA[5:2]	SSI0	1	1	0	0	0x1
PB[3:2]	I <sup>2</sup> C0	1	1	0	0	0x1
PC[3:0]	JTAG	1	1	0	1	0x3

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the **NMI** pin (**PB7**) and the four **JTAG/SWD** pins (**PC[3:0]**). Writes to protected bits of the **GPIOAFSEL** register, **GPIOPUR** register, **GPIO Pull-Down Select (GPIOPDR)** register (see page 319), and **GPIODEN** register are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 323) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 324) have been set.

#### GPIO Pull-Up Select (GPIOPUR)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000

 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x510

Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PUE	R/W	-	Pad Weak Pull-Up Enable  Value Description 1 The corresponding pin has a weak pull-up resistor. 0 The corresponding pin is not affected.  Setting a bit in the <b>GPIOPDR</b> register clears the corresponding bit in the <b>GPIOPUR</b> register. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.  The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 9-1 on page 292.

## Register 16: GPIO Pull-Down Select (GPIOPDR), offset 0x514

The **GPIOPDR** register is the pull-down control register. When a bit is set, a weak pull-down resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPDR** automatically clears the corresponding bit in the **GPIO Pull-Up Select (GPIOPUR)** register (see page 317).

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the **NMI** pin (**PB7**) and the four **JTAG/SWD** pins (**PC[3:0]**). Writes to protected bits of the **GPIOAFSEL** register, **GPIOPUR** register, **GPIO Pull-Down Select (GPIOPDR)** register (see page 319), and **GPIODEN** register are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 323) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 324) have been set.

### GPIO Pull-Down Select (GPIOPDR)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000

 GPIO Port H (APB) base: 0x4002.7000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (APB) base: 0x4003.D000  
 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x514  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PDE	R/W	0x00	Pad Weak Pull-Down Enable

#### Value Description

- |   |  |
|---|--|
| 1 | The corresponding pin has a weak pull-down resistor. |
| 0 | The corresponding pin is not affected.               |

Setting a bit in the **GPIOPUR** register clears the corresponding bit in the **GPIOPDR** register. The change is effective on the second clock cycle after the write if accessing GPIO via the APB memory aperture. If using AHB access, the change is effective on the next clock cycle.

### Register 17: GPIO Slew Rate Control Select (GPIOSLR), offset 0x518

The **GPIOSLR** register is the slew rate control register. Slew rate control is only available when using the 8-mA drive strength option via the **GPIO 8-mA Drive Select (GPIODR8R)** register (see page 315).

#### GPIO Slew Rate Control Select (GPIOSLR)

GPIO Port A (APB) base: 0x4000.4000  
 GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (APB) base: 0x4000.5000

 GPIO Port J (AHB) base: 0x4006.0000  
 Offset 0x518  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	SRL	R/W	0x00	Slew Rate Limit Enable (8-mA drive only)

**Value Description**

- 1 Slew rate control is enabled for the corresponding pin.
- 0 Slew rate control is disabled for the corresponding pin.

**Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C**

**Note:** Pins configured as digital inputs are Schmitt-triggered.

The **GPIODEN** register is the digital enable register. By default, with the exception of the GPIO signals used for JTAG/SWD function, all other GPIO signals are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin in a digital function (either GPIO or alternate function), the corresponding **GPIODEN** bit must be set.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is currently provided for the **NMI** pin (**PB7**) and the four JTAG/SWD pins (**PC[3:0]**). Writes to protected bits of the **GPIODEN** register, **GPIOPUR** register, **GPIO Pull-Down Select (GPIOPDR)** register (see page 319), and **GPIODEN** register are not committed to storage unless the **GPIO Lock (GPIOLCK)** register (see page 323) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 324) have been set.

				Value Description
				0 The digital functions for the corresponding pin are disabled.
				1 The digital functions for the corresponding pin are enabled.
				The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 9-1 on page 292.

## Register 19: GPIO Lock (GPIOLOCK), offset 0x520

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 324). Writing 0x4C4F.434B to the **GPIOLOCK** register unlocks the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x0000.0001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x0000.0000.

Bit/Field	Name	Type	Reset	Description
31:0	LOCK	R/W	0x0000.0001	GPIO Lock

A write of the value 0x4C4F.434B unlocks the **GPIO Commit (GPIOCR)** register for write access. A write of any other value or a write to the **GPIOCR** register reapplies the lock, preventing any register updates.

A read of this register returns the following values:

Value	Description
0x0000.0001	The <b>GPIOCR</b> register is locked and may not be modified.
0x0000.0000	The <b>GPIOCR</b> register is unlocked and may be modified.

### Register 20: GPIO Commit (GPIOCR), offset 0x524

The **GPIOCR** register is the commit register. The value of the **GPIOCR** register determines which bits of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, and **GIODEN** registers are committed when a write to these registers is performed. If a bit in the **GPIOCR** register is cleared, the data being written to the corresponding bit in the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GIODEN** registers cannot be committed and retains its previous value. If a bit in the **GPIOCR** register is set, the data being written to the corresponding bit of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GIODEN** registers is committed to the register and reflects the new value.

The contents of the **GPIOCR** register can only be modified if the status in the **GPIOLOCK** register is unlocked. Writes to the **GPIOCR** register are ignored if the status in the **GPIOLOCK** register is locked.

**Important:** This register is designed to prevent accidental programming of the registers that control connectivity to the NMI and JTAG/SWD debug hardware. By initializing the bits of the **GPIOCR** register to 0 for **PB7** and **PC[3:0]**, the NMI and JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the **GPIOLOCK**, **GPIOCR**, and the corresponding registers.

Because this protection is currently only implemented on the NMI and JTAG/SWD pins on **PB7** and **PC[3:0]**, all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GIODEN** register bits of these other pins.

7:0	CR	-	-	GPIO Commit
-----	----	---	---	-------------

Value Description

- 1 The corresponding **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GIODEN** bits can be written.
- 0 The corresponding **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GIODEN** bits cannot be written.

**Note:** The default register type for the **GPIOCR** register is RO for all GPIO pins with the exception of the **NMI** pin and the four JTAG/SWD pins (**PB7** and **PC[3:0]**). These five pins are currently the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the **NMI** pin and the four JTAG/SWD pins (**PB7** and **PC[3:0]**). To ensure that the JTAG port is not accidentally programmed as a GPIO, these four pins default to non-committable. To ensure that the **NMI** pin is not accidentally programmed as the non-maskable interrupt pin, it defaults to non-committable. Because of this, the default reset value of **GPIOCR** for GPIO Port B is 0x0000.007F while the default reset value of **GPIOCR** for Port C is 0x0000.00F0.

### Register 21: GPIO Analog Mode Select (GPIOAMSEL), offset 0x528

**Important:** This register is only valid for ports D and E, the corresponding base addresses for the remaining ports are not valid.

If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be set to disable the analog isolation circuit.

The **GPIOAMSEL** register controls isolation circuits to the analog side of a unified I/O pad. Because the GPIOs may be driven by a 5-V source and affect analog operation, analog circuitry requires isolation from the pins when they are not used in their analog function.

Each bit of this register controls the isolation circuitry for the corresponding GPIO signal. For information on which GPIO pins can be used for ADC functions, refer to Table 25-5 on page 990.

3:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

### Register 22: GPIO Port Control (GPIOCTL), offset 0x52C

The **GPIOCTL** register is used in conjunction with the **GPIOAFSEL** register and selects the specific peripheral signal for each GPIO pin when using the alternate function mode. Most bits in the **GPIOAFSEL** register are cleared upon reset, therefore most GPIO pins are configured as GPIOs by default. When a bit is set in the **GPIOAFSEL** register, the corresponding GPIO signal is controlled by an associated peripheral. The **GPIOCTL** register selects one out of a set of peripheral functions for each GPIO, providing additional flexibility in signal definition. For information on the configuration options, refer to Table 25-5 on page 990. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 9-1 on page 292.

**Important:** All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**) with the exception of the pins shown in Table 9-1. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

Table 9-8. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GIODEN	GPIOPDR	GPIOPUR	GPIOCTL

## 10 External Peripheral Interface (EPI)

The External Peripheral Interface is a high-speed parallel bus for external peripherals or memory. It has several modes of operation to interface gluelessly to many types of external devices. The External Peripheral Interface is similar to a standard microprocessor address/data bus, except that it must typically be connected to just one type of external device. Enhanced capabilities include  $\mu$ DMA support, clocking control and support for external FIFO buffers.

The EPI has the following features:

- 16-bit dedicated parallel bus for external peripherals and memory
- Memory interface supports contiguous memory access independent of data bus width, thus enabling code execution directly from SDRAM, SRAM and Flash memory
- Blocking and non-blocking reads
- Processor from timing details through use of an internal write FIFO
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for read and write
  - Read channel request asserted by programmable levels on the internal non-blocking read FIFO (NBRFIFO)
  - Write channel request asserted by empty on the internal write FIFO (WFIFO)

The EPI supports three primary functional modes: Synchronous Dynamic Random Access Memory (SDRAM) mode, Traditional Host-Bus mode, and General-Purpose mode. The EPI module also provides custom GPIOs; however, unlike regular GPIOs, the EPI module uses a FIFO in the same way as a communication mechanism and is speed-controlled using clocking.

- Synchronous Dynamic Random Access Memory (SDRAM)
  - Supports x16 (single data rate) SDRAM at up to 50 MHz
  - Supports low-cost SDRAMs up to 64 MB (512 Mb)
  - Includes automatic refresh and access to all banks/rows
  - Includes a Sleep/Standby mode to keep contents active with minimal power draw
  - Multiplexed address/data interface for reduced pin count
- Host-bus
  - Traditional x8 MCU bus interface capabilities
  - Similar device compatibility options as PIC, ATmega, 8051, and others
  - Access to SRAM, NOR Flash, and other devices, with up to 1 MB of addressing
  - Support of both muxed and de-muxed address and data

- Access to a range of devices supporting the non-address FIFO x8 interface variant, with support for external FIFO (XFIFO) `EMPTY` and `FULL` signals
- Speed controlled, with read and write data wait-state counters
- Manual chip-enable (or use extra address pins)
- General Purpose
  - Wide parallel interfaces for fast communications with CPLDs and FPGAs
  - Data widths up to 32-bits
  - Data rates up to 150 Mbytes/second
  - Optional “address” sizes from 4-bits to 16-bits
  - Optional clock output, read/write strobes, framing (with counter-based size), and clock-enable input
- General parallel GPIO
  - 1 to 32 bits, FIFOed with speed control
  - Useful for custom peripherals or for digital data acquisition and actuator controls

## 10.1 EPI Block Diagram

Figure 10-1 on page 343 provides a block diagram of a Stellaris<sup>®</sup> EPI module.

**Figure 10-1. EPI Block Diagram**

## 10.2 Functional Description

The EPI controller provides a glueless, programmable interface to a variety of common external peripherals such as SDRAM, Host Bus x8 devices, RAM, Flash memory, CPLDs and FPGAs. In addition, the EPI controller provides custom GPIO that can use a FIFO with speed control by using either the internal write FIFO (WFIFO) or the non-blocking read FIFO (NBRFIFO). The WFIFO can hold 4 words of data that are written to the external interface at the rate controlled by the **EPI Main Baud Rate (EPIBAUD)** register. The NBRFIFO can hold 8 words of data and samples at the rate controlled by the **EPIBAUD** register. The advantage of this solution is that when using regular GPIO, the access rate can vary due arbitration to the GPIO module and delays across any bus bridges. Blocking reads stall the CPU until the transaction completes. Non-blocking reads are performed in the background and allow the processor to continue operation. In addition, write data can also be stored in the WFIFO to allow multiple writes with no stalls.

Main read and write operations can be performed in subsets of the range 0x6000.0000 to 0xCFFF.FFFF. A read from an address mapped location uses the offset and size to control the address and size of the external operation. When performing a multi-value load, the read is done as a burst (when available) to maximize performance. A write to an address mapped location uses the offset and size to control the address and size of the external operation. When performing a multi-value store, the write is done as a burst (when available) to maximize performance.

### 10.2.1 Non-blocking reads

The EPI Controller supports a special kind of read called a non-blocking read, also referred to as a posted read. Where a normal read stalls the processor or  $\mu$ DMA until the data is returned, a non-blocking read is performed in the background.

A non-blocking read is configured by writing the start address into a **EPIRADDRx** register, the size per transaction into a **EPIRSIZEx** register, and then the count of operations into a **EPIRPSTDx** register. After each read is completed, the result is written into the NBRFIFO and the **EPIRADDRx** register is incremented by the size (1, 2, or 4).

If the NBRFIFO is filled, then the reads pause until space is made available. The NBRFIFO can be configured to interrupt the processor or trigger the  $\mu$ DMA based on fullness using the **EPIFIFOLVL** register. By using the trigger/interrupt method, the  $\mu$ DMA (or processor) can keep space available in the NBRFIFO and allow the reads to continue unimpeded.

When performing non-blocking reads, the SDRAM controller issues two additional read transactions after the burst request is terminated. The data for these additional transfers is discarded. This situation is transparent to the user other than the additional EPI bus activity and can safely be ignored.

Two non-blocking read register sets are available to allow sequencing and ping-pong use. When one completes, the other then activates. So, for example, if 20 words are to be read from 0x100 and 10 words from 0x200, the **EPIRPSTD0** register can be set up with the read from 0x100 (with a count of 20), and the **EPIRPSTD1** register can be set up with the read from 0x200 (with a count of 10). When **EPIRPSTD0** finishes (count goes to 0), the **EPIRPSTD1** register then starts its operation. The NBRFIFO has then passed 30 values. When used with the  $\mu$ DMA, it may transfer 30 values (simple sequence), or the primary/alternate model may be used to handle the first 20 in one way and the second 10 in another. It is also possible to reload the **EPIRPSTD0** register when it is finished (and the **EPIRPSTD1** register is active); thereby, keeping the interface constantly busy.

To cancel a non-blocking read, the **EPIRPSTDx** register is cleared. Care must be taken, however if the register set was active to drain away any values read into the NBRFIFO and ensure that any read in progress is allowed to complete.

To ensure that the cancel is complete, the following algorithm is used (using the **EPIRPSTD0** register for example):

```

EPIRPSTD0 = 0;
while ((EPISTAT & 0x11) == 0x10)
; // we are active and busy
// if here, then other one is active or interface no longer busy
cnt = (EPIRADDR0 – original_address) / EPIRSIZ0E; // count of values read
cnt -= values_read_so_far;
// cnt is now number left in FIFO
while (cnt--)
value = EPIREADFIFO; // drain

```

The above algorithm can be optimized in code; however, the important point is to wait for the cancel to complete because the external interface could have been in the process of reading a value when the cancel came in, and it must be allowed to complete.

## 10.2.2 DMA Operation

The  $\mu$ DMA can be used to efficiently transfer data to and from the NBRFIFO and the WFIFO. The  $\mu$ DMA has one channel for write and one for read. The write channel can be configured to copy values to the WFIFO when the WFIFO is empty. For non-blocking reads, the start address, the size per transaction, and the count of elements must be programmed in the  $\mu$ DMA. The NBRFIFO level at which the  $\mu$ DMA triggers the read accesses must also be programmed. Note that both non-blocking read channels can be used, and they fill the NBRFIFO such that one runs to completion, then the next one starts (they do not interleave). For blocking reads, any  $\mu$ DMA channel can be used as a memory-to-memory transfer (or memory to peripheral, where some other peripheral is used). In this situation, the  $\mu$ DMA is blocked when reading, thus the  $\mu$ DMA is not able to service another channel until the read is done. As a result, the arbitration size should normally be programmed to one access at a time. See “Micro Direct Memory Access ( $\mu$ DMA)” on page 226 for more information on configuring the  $\mu$ DMA.

## 10.3 Initialization and Configuration

To enable and initialize the EPI block, the following steps are necessary:

1. Enable the EPI block using the **RCGC1** register. See page 167.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.
3. Set the GPIO **AFSEL** bits for the appropriate pins. See page 311. To determine which GPIOs to configure, see Table 25-5 on page 990.
4. Set the GPIO current level and/or slew rate as specified for the mode selected. See page 313 and page 320.
5. Select the mode for the EPI block to SDRAM, HB8, or general parallel use, using the **MODE** field in the **EPI Configuration (EPICFG)** register. Set the mode-specific details (if needed) using the appropriate mode configuration **EPI xxx Configuration (EPIxxxCFG)** and **EPI xxx**

**Configuration 2 (EPIxxxCFG2)** registers. Set the **EPI Main Baud Rate (EPIBAUD)** register if the baud rate must be slower than the core clock rate.

6. Configure the address mapping using the **EPI Address Map (EPIADDRMAP)** register. The selected start address and range is dependent on the type of external device and maximum address (as appropriate). For example, for a 512-MB SDRAM, program the `ERADR` field to 0x1 for address 0x60000000 or 0x2 for address 0x80000000; and program the `ERSZ` field to 0x3 for 512 MB. If using a non-mode and no address at all, program the `EPADR` field to 0x1 for address 0xA0000000 or 0x2 for address 0xC0000000; and program the `EPSZ` field to 0x0 for 256 bytes.
7. To read or write directly, use the mapped address area (configured with the **EPIADDRMAP** register). Up to 4 or 5 writes can be performed at once without blocking. Each read is blocked until the value is retrieved.
8. To perform a non-blocking read, see “Non-blocking reads” on page 344.

The following sub-sections describe the initialization and configuration for each of the modes of operation. Care must be taken to initialize everything properly to ensure correct operation. Control of the GPIO states is also important, as changes may cause the external device to interpret pin states as actions or commands (see “Register Descriptions” on page 300). Normally, a pull-up or pull-down is needed on the board to at least control the chip-select or chip-enable as the Stellaris® GPIOs come out of reset in tri-state.

The Table 10-1 on page 346 table defines how EPI module signals should be connected to various external peripherals. The table applies when using a x16 SDRAM up to 512 MB.

**Table 10-1. EPI Signal Connections**

EPI Signal	SDRAM Signal <sup>a</sup>		Host Bus 8 Signal (MODE =0x0 in EPIHB8CFG register)	Host Bus 8 Signal (MODE =0x1 in EPIHB8CFG register)	Host Bus 8 Signal (MODE =0x3 in EPIHB8CFG register)	General-Purpose Signal (D8, A20)	General- Purpose Signal (D16, A12)	General- Purpose Signal (D24, A4)	General- Purpose Signal (D32)

EPI31	CLK	Clock	Clock	Clock	Clock	Clock	Clock	D31

a. If 2 signals are listed, connect the EPI signal to both pins.

b. Only for 256/512 Mb SDRAMs

c. A1 represents the system address bit 1 for 16-bit data access. If this signal is connected to a device that only has 16-bit data access, then EPI16 should be connected to A0. EPI[27:17] should also be connected to A[11:1] in this case.

d. A2 represents the system address bit 2 for 32-bit data access. If this signal is connected to a device that only has 24-bit data access then EPI24 should be connected to A0. EPI[27:25] should also be connected to A[3:1] in this case.

e. This signal is iRDY if the RDYEN bit in the **EPIGPCFG** register is set.

f. The CSCFG field in the **EPIHB8CFG2** register should be configured to 0x0. This option creates an ALE pulse during the address cycle preceding the read/write cycle.

g. The CSCFG field in the **EPIHB8CFG2** register should be configured to 0x1. This option creates a CSn that is active during the read/write cycle.

### 10.3.1 SDRAM mode

When activating the SDRAM mode, it is important to consider a few points:

1. Generally, it takes over 100  $\mu$ s from when the mode is activated to when the first operation is allowed. The SDRAM controller begins the SDRAM initialization sequence as soon as the mode is selected and enabled via the **EPIPCFG** register. It is important that the GPIOs are properly configured before the SDRAM mode is enabled, as the EPI Controller is relying on the GPIO block's ability to drive the pins immediately. As part of the initialization sequence, the LOAD MODE REGISTER command is automatically sent to the SDRAM with a value of 0x27, which sets a CAS latency of 2 and a full page burst length.
2. The **INITSEQ** bit in the **EPI Status (EPISTAT)** register can be checked to determine when the initialization sequence is complete.
3. When using a frequency range and/or refresh value other than the default value, It is important to configure the **FREQ** and **RFSH** fields in the **EPI SDRAM Configuration (EPISDRAMCFG)**

register shortly after activating the mode. After the 100- $\mu$ s startup time, the EPI block must be configured properly to keep the SDRAM contents stable.

4. The `SLEEP` bit in the `EPISDRAMCFG` register may be configured to put the SDRAM into a low-power self-refreshing state. It is important to note that the SDRAM mode must not be disabled once enabled, or else the SDRAM is no longer be clocked and the contents are lost.

The `SIZE` field of the `EPISDRAMCFG` register must be configured correctly based on the amount of SDRAM in the system.

The `FREQ` field must be configured according to the value that represents the range being used. Based on the range selected, the number of external clocks used between certain operations (for example, `PRECHARGE` or `ACTIVATE`) is determined. If a higher frequency is given than is used, then the only downside is that the peripheral is slower (uses more cycles for these delays). If a lower frequency is given, incorrect operation occurs.

The refresh count is based on the external clock speed and the number of rows per bank as well as the refresh period. The `RFSH` field represents how many external clock cycles remain before an `AUTO-REFRESH` is required. The normal formula is:

$$\text{RFSH} = (\text{tRefresh}_{\mu\text{s}} / \text{number\_rows}) / \text{ext\_clock\_period}$$

A refresh period is normally 64 ms, or 64000  $\mu$ s. The number of rows is normally 4096 or 8192. The `ext_clock_period` is a value expressed in  $\mu$ sec and is derived by dividing 1000 by the clock speed expressed in MHz. So, 50 MHz is  $1000/50=20$  ns, or 0.02  $\mu$ s. A typical SDRAM is 4096 rows per bank if the core clock is running at 50 MHz with an `EPIBAUD` register value of 0:

$$\text{RFSH} = (64000/4096) / 0.02 = 15.625 \mu\text{s} / 0.02 \mu\text{s} = 781.25$$

The default value in the `RFSH` field is 750 decimal or 0x2EE to allow for a margin of safety and providing 15  $\mu$ s per refresh. It is important to note that this number should always be smaller or equal to what is required by the above equation. For example, if running the external clock at 25 MHz (40 ns per clock period), 390 is the highest number that may be used. Note that the external clock may be 25 MHz when running the core at 25 MHz or when running the core at 50 MHz and setting the `EPIBAUD` register to 1 (divide by 2).

If a number larger than allowed is used, the SDRAM is not refreshed often enough, and data is lost.

See “External Peripheral Interface (EPI)” on page 1004 for timing details for the SDRAM mode.

## 10.3.2 Host Bus Mode

Host Bus supports the traditional 8-bit interface popularized by the 8051 devices. This interface is asynchronous and uses strobe pins to control activity.

### 10.3.2.1 Control Pins

The main three strobes are `ALE` (Address latch enable), `WRn` (write), and `RDn` (sometimes called `OEn`, used for read). Note that the timings are designed for older logic and so are hold-time vs. setup-time specific. To ensure proper operation on this bus, the EPI block uses two core clocks per transition to allow significant skewing of control vs. data signals. So, for example, `ALE` rises one EPI clock before `ADDR/DA` is asserted. Likewise, `ALE` falls (latch point) one EPI clock before `DA` changes or tri-states. The same approach is used for the `WRn` and `RDn/OEn` strobes.

The `ALE` can be changed to `CSn` through the **EPI Host-Bus Configuration 2 (EPIHB8CFG2)** register. The `ALE` is best used for Host-Bus muxed mode in which EPI address and data pins are shared. All Host-Bus accesses have an address phase then a data phase. The `ALE` indicates to an

external latch to capture the address then hold until the data phase. CSn is best used for Host-Bus unmuxed mode in which EPI address and data pins are separate. The CSn indicate when the address and data phases of a read or write access is occurring.

For FIFO mode, the ALE is not used, and two input holds are optionally supported to gate input and output to what the XFIFO can handle.

### 10.3.2.2 Speed of Transactions

The COUNT field **EPIBAUD** must be configured to set the main transaction rate based on what the slave device can support (including wiring considerations). The main control transitions are normally  $\frac{1}{2}$  the baud rate (COUNT = 1) because the EPI block forces data vs. control to change on alternating clocks.

Additionally, the Host Bus mode provides read and write wait states for the data portion to support different classes of device. These wait states stretch the data period (hold the rising edge of data strobe) and may be used in all four sub-modes. The wait states are set using the WRWS and RDWS bits in the **EPI Host-Bus 8 Configuration (EPIHB8CFG)** register.

### 10.3.2.3 Sub-Modes of Host Bus 8

The EPI controller supports four variants of the host bus model using 8 bits of data in all four cases. The four sub-modes are selected using the MODE bits in the **EPIHB8CFG** register, and are:

1. Address and data are muxed (address and data share EPI[7:0] with additional address at EPI[19:8]). This scheme is used by many 8051 devices, some Microchip PIC parts, and some ATmega parts. When used for standard SRAMs, a latch must be used between the microcontroller and the SRAM. This sub-mode is provided for compatibility with existing devices that support data transfers without a latch (for example, LCD controllers or CPLDs). In general, the de-muxed sub-mode should normally be used. The ALE configuration should be used in this mode, as all Host-Bus accesses have an address phase followed by a data phase. The ALE indicates to an external latch to capture the address then hold until the data phase. The ALE configuration is controlled by configuring the CSCFG field to be 0x0 in the **EPIHB8CFG2** register. The CSn is best used for Host-Bus 8 unmuxed mode which EPI address and data pins are separate. The CSn will indicate when the address and data phases of a read or write access is occurring.
2. Address and data are separate with 8 bits of data and up to 20 bits of address (1MB). This scheme is used by more modern 8051 devices, as well as some PIC and ATmega parts. This mode is generally used with real SRAMs, many EEPROMS, and many NOR Flash memory devices. Note that there is no hardware command write support for Flash memory devices; this mode should only be used for Flash memory devices programmed at manufacturing time. If a Flash memory device must be written and does not support a direct programming model, the command mechanism must be performed in software. The CSn configuration should be used in this mode. The CSn signals indicate when the address and data phases of a read or write access is occurring. The CSn configuration is controlled by configuring the CSCFG field to be 0x1 in the **EPIHB8CFG2** register.
3. SRAM fast mode where address and data are separate. This sub-mode is used for real SRAMs which can be read more quickly by only changing the address (and not using RDn/OEn strobing).
4. FIFO mode uses 8 bits of data, removes ALE and address pins and optionally adds external XFIFO FULL/EMPTY flag inputs. This scheme is used by many devices, such as radios, communication devices (including USB2 devices), and some FPGA configurations (FIFO through block RAM). This sub-mode provides the data side of the normal Host Bus interface, but is

paced by the FIFO control signals. It is important to consider that the XFIFO FULL/EMPTY control signals may stall the interface and could have an impact on blocking read latency from the processor or  $\mu$ DMA.

See “External Peripheral Interface (EPI)” on page 1004 for timing details for the Host-Bus 8 mode.

### 10.3.3 General-Purpose Mode

The **General-Purpose Mode Configuration (EPIGPCFG)** register is used to control the size of control, data, and address pins, if used. The general-purpose configuration can be used for custom interfaces with FPGAs, CPLDs, and digital data acquisition and actuator control.

It is designed for three general types of use:

- Extremely high-speed clocked interfaces to FPGAs and CPLDs. Three sizes of data and optional address are supported. Framing and clock-enable functions permit more optimized interfaces.
- General parallel GPIO. From 1 to 31 pins may be written or read, with the speed controlled by the **EPIBAUD** register baud rate (when used with the WFIFO and/or the NBRFIFO) or by the rate of accesses from software or  $\mu$ DMA.
- General custom interfaces of any speed.

The configuration allows for choice of an output clock (free-running or gated), a framing signal (with frame size), a clock-enable input (to stretch transactions), a READ and WRITE strobe, an address (of varying sizes), and data (of varying sizes). Additionally, provisions are made for separating data and address phases.

To understand the interface’s possibilities, it is important to understand the optional features:

- Use of output clock or not (controlled by the **CLKPIN** bit in the **EPIGPCFG** register). Unlocked uses include general purpose I/O and asynchronous interfaces (optionally using READ and WRITE strobes). Clocked interfaces allow for higher speeds and are much easier to connect to FPGAs and CPLDs (which usually include input clocks).
- Clock, if used, may be free running or gated (using the **CLKGATE** bit in the **EPIGPCFG** register). A free-running clock requires another method for determining when data is live, such as the frame pin or READ/WRITE strobes. A gated clock approach uses a setup time model in which the clock controls when transactions are starting and stopping. Note that a gated clock can only be used when the **EPIBAUD** register has a value other than 0 (meaning the output clock is less than the core clock). The gated clock is held low until a new transaction is started and goes high at the end of the cycle where READ/WRITE/FRAME and address (and data if write) are emitted.
- Clock-enable input (iRDY) from the external device (controlled by the **RDYEN** bit in the **EPIGPCFG** register). The clock-enable signal uses **EPI27** and may only be used with a free-running clock. **RDYEN** gates transactions, no matter what state they are in. In addition, **RDYEN** is registered internally and holds the transaction state across multiple clocks if clock-disabled. Generally, **RDYEN** should be changed before the falling edge of the external clock. If the **EPIBAUD** register is 0, an external device can stretch the current state by clearing the **RDYEN** bit.
- Frame pin (controlled by the **FRMPIN** bit in the **EPIGPCFG** register). The frame pin may be used whether the clock is output or not, and whether the clock is free running or not. It may also be used along with the clock-enable. The frame may be a pulse (one clock) or may be 50/50 split across the frame size (controlled by the **FRM50** bit in the **EPIGPCFG** register). The frame count (the size of the frame as specified by the **FRMCNT** field in the **EPIGPCFG** register) may be between

1 and 15 clocks for pulsed and between 2 and 30 clocks for 50/50. The frame pin counts transactions and not clocks; a transaction is any clock where the READ or WRITE strobe is high (if used). So, if the `FRMCNT` bit is set, then the frame pin pulses every other transaction; if 2-cycle reads and writes are used, it pulses every other address phase. `FRM50` must be used with this in mind as it may hold state for many clocks waiting for the next transaction.

- READ and WRITE strobes may be used (controlled by the `RW` bit in the **EPIGPCFG** register). For interfaces where the direction is known (in advance, related to frame size, or other means), these strobes are not needed. For most other interfaces, READ and WRITE are used so the external peripheral knows what transaction is taking place, and if any transaction is taking place. READ is used in conjunction with separating the address and data phases (2-cycle mode), as explained below.
- Separation of address/request and data phases may be used on reads and writes using the `WR2CYC` and `RD2CYC` bits in the **EPIGPCFG** register. This configuration allows the external peripheral extra time to act and is more commonly used on reads. When configured to use an address as specified by the `ASIZE` field in the **EPIGPCFG** register, the address is emitted on the READ cycle (first cycle) and data is expected to be returned on the next cycle (when READ is not asserted). If no address is used, then READ is asserted on the first cycle and data is captured on the second cycle (when READ is not asserted), allowing more setup time for data. If single-cycle reads are used, then data is expected to be available on the same cycle as READ using the specified setup time. To use single-cycle reads, the external peripheral must have either fast combinatorial logic (relative to clock period) or must be able to setup the data in advance.

For writes, the output may be in one or two cycles. In the two-cycle case, the address (if any) is emitted on the first cycle with WRITE and the data is emitted on the second cycle (with WRITE not asserted). Although split address and write data phases are not normally needed for logic reasons, it may be useful to make read and write timings match. If 2-cycle reads or writes are used, the `RW` bit is automatically set.

- Address may be emitted (controlled by the `ASIZE` field in the **EPIGPCFG** register). The address may be 4 bits (16 possible values), 12 bits (4096 possible values), or 20 bits (1 M possible values). Size of address limits size of data, for example, 4 bits of address supports 20 bits data in non-multiplex mode. Address comes from the bottom bits of the address used for the transaction by the processor or  $\mu$ DMA. The address signals may be used by the external peripheral as an address, code (command), or for other unrelated uses (such as a chip enable).
- Data may be 8 bits, 16 bits, 24 bits, or 32 bits (controlled by the `DSIZE` field in the **EPIGPCFG** register). 32-bit data cannot be used with address or clock or any other signal. 24-bit data can only be used with 4-bit address or no address. 32-bit data requires that either the `WR2CYC` bit or the `RD2CYC` bit in the **EPIGPCFG** register is set.
- When using the EPI as a GPIO interface, writes are FIFOed (up to 4 can be held at any time), and up to 32 pins are changed using the **EPIBAUD** clock rate. So, output pin control can be very precisely controlled as a function of time. By contrast, when writing to normal GPIOs, writes can only occur 8-bits at a time and take up to two clock cycles to complete. In addition, the write itself may be further delayed by the bus due to DMA or draining of a previous write. With both GPIO and EPI, reads may be performed directly, in which case the current pin states are read back. With EPI, the non-blocking interface may also be used to perform reads based on a fixed time rule via the **EPIBAUD** clock rate.

See “External Peripheral Interface (EPI)” on page 1004 for timing details for the General-Purpose mode.

## 10.4 Register Map

Table 10-2 on page 352 lists the EPI registers. The offset listed is a hexadecimal increment to the register's address, relative to the base address of 0x400D.0000. Note that the EPI controller clock must be enabled before the registers can be programmed (see page 167).

**Note:** A back-to-back write followed by a read of the same register reads the value that written by the first write access, not the value from the second write access. (This situation only occurs when the processor core attempts this action, the  $\mu$ DMA does not do this.). To read back what was just written, another instruction must be generated between the write and read. Read-write does not have this issue, so use of read-write for clear of error interrupt cause is not affected.

**Table 10-2. External Peripheral Interface (EPI) Register Map**

## 10.5 Register Descriptions

This section lists and describes the EPI registers, in numerical order by address offset.

## Register 1: EPI Configuration (EPICFG), offset 0x000

**Important:** The programming of the `MODE` field determines which configuration register is accessed for offsets 0x010 and 0x014. Any write to the EPICFG register resets the register contents at offsets 0x010 and 0x014.

The configuration register is used to enable the block, select a mode, and select the basic pin use (based on the mode). Note that attempting to program an undefined `MODE` field clears the `BLKEN` bit and disables the EPI controller.

0x3-0xF	Reserved													

## Register 2: EPI Main Baud Rate (EPIBAUD), offset 0x004

The main core clock is used internally to the EPI Controller. The baud rate counter can be used to divide the core clock down to control the speed on the external interface. If the mode selected emits an external clock, this register defines the clock emitted. If the mode selected does not use a clock, this register controls the speed of changes on the external interface. Care must be taken to program this register properly so that the speed of the external bus corresponds to the speed of the external peripheral and puts acceptable current load on the pins.

The COUNT is not a straight divider or count, but is instead calculated using the following formula:

$$\frac{1}{\left(\frac{\text{COUNT}}{2} + 1\right) \times 2}$$

So, for example, a COUNT of 0x0001 results in a clock rate of  $\frac{1}{2}$ (core clock); a COUNT of 0x0002 or 0x0003 results in a clock rate of  $\frac{1}{4}$ (core clock).

### EPI Main Baud Rate (EPIBAUD)

Base 0x400D.0000

Offset 0x004

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	COUNT	R/W	0x0000	Baud Rate Counter  This bit field contains a counter used to divide the system clock by the count. The maximum frequency for the external baud clock is 40 MHz.  A count of 0 means the system clock is used as is.

### Register 3: EPI SDRAM Configuration (EPISDRAMCFG), offset 0x010

**Important:** To access this register, the `MODE` field in the `EPICFG` register must be 0x1.

The SDRAM Configuration register is used to specify several parameters for the SDRAM controller. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the SDRAM mode is selected again, the values must be reinitialized.

The SDRAM interface designed to interface to x16 SDR SDRAMs of 64 MHz or higher, with the address and data pins overlapped (wire ORed on the board). See Table 10-1 on page 346 for pin assignments.

1:0	SIZE	R/W	0x0	<p>Size of SDRAM</p> <p>The value of this field affects address pins and behavior.</p> <p>Value Description</p> <p>0x0 64Mb (8MB)</p> <p>0x1 128Mb (16MB)</p> <p>0x2 256Mb (32MB)</p> <p>0x3 512Mb (64MB)</p>

## Register 4: EPI Host-Bus 8 Configuration (EPIHB8CFG), offset 0x010

**Important:** To access this register, the `MODE` field in the `EPICFG` register must be 0x2.

The Host Bus 8 sub-configuration register is activated when the HB8 mode is selected. The HB8 mode supports muxed address/data (overlay of lower 8 address and all 8 data pins), separated address/data, and address-less FIFO mode. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the SDRAM mode is selected again, the values must be reinitialized.

It is intended to support SRAMs, Flash memory (read), FIFOs, CPLDs/FPGAs, and devices with an MCU/HostBus slave or 8-bit FIFO interface support.

When activated, certain pins are assigned as follows:

- `EPI31` is assigned to clock
- `EPI30` is assigned to ALE/CS<sub>n</sub> (not used when using an external FIFO)
- `EPI29` is assigned to WR<sub>n</sub> (or WR if `WRHIGH` is set)
- `EPI28` is assigned to RD<sub>n</sub>/OEn
- `EPI27` down to `EPI8` are assigned to address for all but FIFO sub-mode
- `EPI27` is assigned to FFULL (XFIFO full) when in FIFO sub-mode and `XFFEN` is set
- `EPI26` is assigned to FEMPTY (XFIFO empty) when in FIFO sub-mode and `XFEEN` is set
- `EPI7` down to `EPI0` are assigned to data (D[7:0]) in all sub-modes, and address low (A[7:0]) in muxed AD sub-mode

See Table 10-1 on page 346 for more on pin assignments.

If less address pins are required, the corresponding GPIO's `AFSEL` (page 311) should not be enabled (so the EPI controller does not drive those pins, and they are available as standard GPIOs).

There is no direct chip enable (CE) model. Instead, CE can be handled in one of three ways:

1. Manually control via GPIOs.
2. Associate one or more upper address pins to CE. Because CE is normally CEn, lower addresses are not used. For example, if pins `EPI27` and `EPI26` are used for Device 1 and 0 respectively, then address 0x6800.0000 accesses Device 0 (Device 1 has its CEn high), and 0x6400.0000 accesses Device 1 (Device 0 has its CEn high). The pull-up behavior on the corresponding GPIOs must be properly configured to ensure that the pins are disabled when the interface is not in use.
3. With certain SRAMs, the ALE can be used as CEn because the address remains stable after the ALE strobe. The subsequent WR<sub>n</sub> or RD<sub>n</sub> signals write or read when ALE is low thus providing CEn functionality.

EPI Host-Bus 8 Configuration (EPIHB8CFG)

Base 0x400D.0000  
 Offset 0x010  
 Type R/W, reset 0x0000.FF00

Bit/Field	Name	Type	Reset	Description

Bit/Field	Name	Type	Reset	Description
1:0	MODE	R/W	0x0	<p>Host Bus Sub-Mode</p> <p>This field determines which of four Host Bus 8 sub-modes to use. Sub-mode use is determined by the connected external peripheral.</p> <p>Value Description</p> <p>0x0 ADMUX – AD[7:0] Data and Address are muxed on EPI[7:0] and additional address is at EPI[27:8].</p> <p>0x1 ADNONMUX – D[7:0] Data and address are separate. D[7:0] are on EPI[7:0] and A[19:0] are on EPI[27:8].</p> <p>0x2 SRAM This mode is the same as ADNONMUX, but uses address switch for multiple reads vs. OEn.</p> <p>0x3 XFIFO – D[7:0] This mode adds XFIFO controls with sense of XFIFO full and XFIFO empty. This mode uses no address or ALE.</p>

## Register 5: EPI General-Purpose Configuration (EPIGPCFG), offset 0x010

**Important:** To access this register, the `MODE` field in the `EPICFG` register must be 0x0.

The General-Purpose configuration register is used to control the size of control, data, and address pins, if used. This mode can be used for custom interfaces with FPGAs, CPLDs, and for digital data acquisition and actuator control. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the SDRAM mode is selected again, the register the values must be reinitialized.

This mode is designed for 3 general types of use:

- Extremely high-speed clocked interfaces to FPGAs and CPLDs, with 3 sizes of data and optional address. Framing and clock-enable permit more optimized interfaces.
- General parallel GPIO. From 1 to 31 pins may be written or read, with the speed controlled by setting the baud rate in the `EPIBAUD` register (when used with the `NBRFIFO` and/or the `WFIFO`) or by rate of accesses from software or  $\mu$ DMA.
- General custom interfaces of any speed.

The configuration allows for choice of an output clock (free running or gated), a framing signal (with frame size), a clock-enable input (to stretch transactions), READ and WRITE strobes, address of varying sizes, and data of varying sizes. Additionally, provisions are made for splitting address and data phases on the external interface.

## Register 8: EPI Address Map (EPIADDRMAP), offset 0x01C

This register enables address mapping. The EPI controller can directly address memory and peripherals. In addition, the EPI controller supports address mapping to allow indirect accesses in the External RAM and External Peripheral areas. Note that use of either one does not affect how the EPI Controller behaves, but care must be taken not to overlap memory regions.

**Register 9: EPI Read Size 0 (EPIRSIZE0), offset 0x020**

**Register 10: EPI Read Size 1 (EPIRSIZE1), offset 0x030**

This register selects the size of transactions when performing non-blocking reads with the **EPIRPSTD** registers. This size affects how the external address is incremented.

The **SIZE** field must match the external data width as configured in the **EPIHB8CFG** or **EPIGPCFG** register (see Table 10-1 on page 346).

SDRAM mode uses a 16-bit data interface. If **SIZE** is 0x1, data is returned on the least significant bits (D[7:0]), and the remaining bits D[31:8] are all zeros, therefore the data on bits D[15:8] is lost.. If **SIZE** is 0x2, data is returned on the least significant bits (D[15:0]), and the remaining bits D[31:16] are all zeros.

Note that changing this register while a read is active has an unpredictable effect.

**EPI Read Size 0 (EPIRSIZE0)**

				0x3 Word (32 bits)

**Register 11: EPI Read Address 0 (EPIRADDR0), offset 0x024**

**Register 12: EPI Read Address 1 (EPIRADDR1), offset 0x034**

This register holds the current address value. When performing non-blocking reads via the **EPIRSTD** registers, this register's value forms the address (when used by the mode). That is, when a **EPIRSTD** register is written with a non-0 value, this register is used as the first address. After each read, it is incremented by the size specified by the corresponding **EPIRSIZE** register. Thus at the end of a read, this register contains the next address for the next read. For example, if the last read was 0x20, and the size is word, then the register contains 0x24. When a non-blocking read is cancelled, this register contains the next address that would have been read had it not been cancelled. For example, if reading by bytes and 0x103 had been read but not 0x104, this register contains 0x104. In this manner, the system can determine the number of values in the NBRFIFO to drain.

Note that changing this register while a read is active has an unpredictable effect due to race condition.

EPI Read Address 0 (EPIRADDR0)

Base 0x400D.0000  
 Offset 0x024  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:29	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28:0	ADDR	R/W	0x000.0000	Current Address Next address to read.

**Register 13: EPI Non-Blocking Read Data 0 (EPIRPSTD0), offset 0x028****Register 14: EPI Non-Blocking Read Data 1 (EPIRPSTD1), offset 0x038**

This register sets up a non-blocking read via the external interface. A non-blocking read is started by writing to this register with the count (other than 0). Clearing this register terminates an active non-blocking read as well as cancelling any that are pending. This register should always be cleared before writing a value other than 0; failure to do so can cause improper operation.

The first address is based on the corresponding **EPIRADDR** register. The address register is incremented by the size specified by the **EPIRSIZE** register after each read. If the size is less than a word, only the least significant bits of data are filled into the NBRFIFO; the most significant bits are cleared.

Note that all three registers may be written using one STM instruction, such as with a structure copy in C/C++.

The data may be read from the **EPIREADFIFO** register after the read cycle is completed. The interrupt mechanism is normally used to trigger the FIFO reads via ISR or  $\mu$ DMA.

If the countdown has not reached 0 and the NBRFIFO is full, the external interface waits until a NBRFIFO entry becomes available to continue.

Note: if a blocking read or write is performed through the address mapped area (at 0x6000.0000 through 0xCFFF.FFFF), any current non-blocking read is paused (at the next safe boundary), and the blocking request is inserted. After completion of any blocking reads or writes, the non-blocking reads continue from where they were paused.

The other way to read data is via the address mapped locations (see the **EPIADDRMAP** register), but this method is blocking (core or  $\mu$ DMA waits until result is returned).

To cancel a non-blocking read, clear this register. To make sure that all values read are drained from the NBRFIFO, the **EPISTAT** register must be consulted to be certain that bits **NBRBUSY** and **ACTIVE** are cleared. One of these registers should not be cleared until either the other **EPIRPSTDx** register becomes active or the external interface is not busy. At that point, the corresponding **EPIRADDR** register indicates how many values were read.

**EPI Non-Blocking Read Data 0 (EPIRPSTD0)**

31:13	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
12:0	POSTCNT	R/W	0x000	Post Count  A write of a non-zero value starts a read operation for that count. Note that it is the software's responsibility to handle address wraparound.  Reading this register provides the current count.  A write of 0 cancels a non-blocking read (whether active now or pending).  Prior to writing a non-zero value, this register must first be cleared.

## Register 15: EPI Status (EPISTAT), offset 0x060

This register indicates which non-blocking read register is currently active; it also indicates whether the external interface is busy performing a write or non-blocking read (it cannot be performing a blocking read, as the bus would be blocked and as a result, this register could not be accessed).

This register is useful for determining which non-blocking read register is active when both are loaded with values and when implementing sequencing or sharing.

This register is also useful when canceling non-blocking reads, as it shows how many values were read by the canceled side.

2:0	COUNT	R	-	FIFO Count Number of filled entries in the NBRFIFO.

**Register 17: EPI Read FIFO (EPIREADFIFO), offset 0x070**

**Register 18: EPI Read FIFO Alias 1 (EPIREADFIFO1), offset 0x074**

**Register 19: EPI Read FIFO Alias 2 (EPIREADFIFO2), offset 0x078**

**Register 20: EPI Read FIFO Alias 3 (EPIREADFIFO3), offset 0x07C**

**Register 21: EPI Read FIFO Alias 4 (EPIREADFIFO4), offset 0x080**

**Register 22: EPI Read FIFO Alias 5 (EPIREADFIFO5), offset 0x084**

**Register 23: EPI Read FIFO Alias 6 (EPIREADFIFO6), offset 0x088**

**Register 24: EPI Read FIFO Alias 7 (EPIREADFIFO7), offset 0x08C**

This register returns the contents of the NBRFIFO or 0 if the NBRFIFO is empty. Each read returns the data that is at the top of the NBRFIFO, and then empties that value from the NBRFIFO. The alias registers can be used with the LDMIA instruction for more efficient operation (for up to 8 registers). See *ARM® Cortex™-M3 Technical Reference Manual* for more information on the LDMIA instruction.

EPI Read FIFO (EPIREADFIFO)

Base 0x400D.0000  
 Offset 0x070  
 Type R, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATA	R	0x0000.0000	Reads Data

This field contains the data that is at the top of the NBRFIFO. After being read, the NBRFIFO entry is removed.

### Register 25: EPI FIFO Level Selects (EPIFIFOLVL), offset 0x200

This register allows selection of the FIFO levels which trigger an interrupt to the core or, more efficiently, a DMA request to the  $\mu$ DMA. The NBRFIFO select triggers on fullness such that it triggers on match or above (more full). The WFIFO triggers on emptiness such that it triggers on match or below (less entries).

It should be noted that the FIFO triggers are not identical to other such FIFOs in Stellaris<sup>®</sup> peripherals. In particular, empty and full triggers are provided to avoid wait states when using blocking operations.

The settings in this register are only meaningful if the  $\mu$ DMA is active or the interrupt is enabled.

Additionally, this register allows protection against writes stalling and notification of performing blocking reads which stall for extra time due to preceding writes. The two functions behave in a non-orthogonal way because read and write are not orthogonal.

The write error bit configures the system such that an attempted write to an already full WFIFO abandons the write and signals an error interrupt to prevent accidental latencies due to stalling writes.

The read error bit configures the system such that after a read has been stalled due to any preceding writes in the WFIFO, the error interrupt is generated. Note that the excess stall is not prevented, but an interrupt is generated after the fact to notify that it has happened.

17	WFERR	R/W	0	Write Full Error

Value Description

- 1 This bit enables the Write Full error interrupt (WTFULL in the EPIIC register) to be generated when a write is attempted and the WFIFO is full. The write stalls until a WFIFO entry becomes available.
- 0 The Write Full error interrupt is disabled. Writes are stalled when the WFIFO is full until a space becomes available but an error is not generated. Note that the Cortex-M3 write buffer may hide that stall if no other memory transactions are attempted during that time.

## Register 26: EPI Write FIFO Count (EPIWFIFOCNT), offset 0x204

This register contains the number of slots currently available in the WFIFO. This register may be used for polled writes to avoid stalling and for blocking reads to avoid excess stalling (due to undrained writes). An example use for writes may be:

```
for (idx = 0; idx < cnt; idx++) {
while (EPIWFIFOCNT == 0) ;
*ext_ram = *mydata++;
}
```

The above code ensures that writes to the address mapped location do not occur unless the WFIFO has room. Although polling makes the code wait (spinning in the loop), it does not prevent interrupts being serviced due to bus stalling.

### EPI Write FIFO Count (EPIWFIFOCNT)

2:0	WTAV	R	0x0	Available Write Transactions The number of write transactions available in the WFIFO. When clear, a write is stalled waiting for a slot to become free (from a preceding write completing).

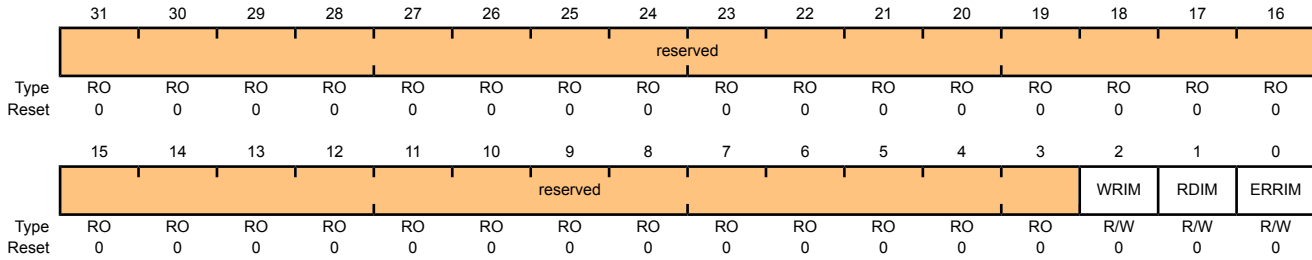

### Register 27: EPI Interrupt Mask (EPIIM), offset 0x210

This register is the interrupt mask set or clear register. For each interrupt source (read, write, and error), a mask value of 1 allows the interrupt source to trigger an interrupt to the interrupt controller; a mask value of 0 prevents the interrupt source from triggering an interrupt.

Note that interrupt masking has no effect on  $\mu$ DMA, which operates off the raw source of the read and write interrupts.

#### EPI Interrupt Mask (EPIIM)

## Register 28: EPI Raw Interrupt Status (EPIRIS), offset 0x214

This register is the raw interrupt status register. On a read, it gives the current state of each interrupt source. A write has no effect.

Note that raw status for read and write is set or cleared based on FIFO fullness as controlled by **EPIFIFOLVL**.

Raw status for error is held until the error is cleared by writing to the **EPIIC** register.

1	A WFIFO Full, a Read Stalled, or a Timeout error has occurred.							
0	An error has not occurred.							

## Register 29: EPI Masked Interrupt Status (EPIMIS), offset 0x218

This register is the masked interrupt status register. On read, it gives the current state of each interrupt source (read, write, and error) after being masked via the **EPIIM** register. A write has no effect.

The values returned are the ANDing of the **EPIIM** and **EPIRIS** registers. If a bit is set in this register, the interrupt is sent to the interrupt controller.

### EPI Masked Interrupt Status (EPIMIS)

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	WRMIS	R	0	Write Masked Interrupt Status
Value Description				
	1			The number of available entries in the WFIFO is within the range specified by the trigger level (the <b>WRFIFO</b> field in the <b>EPIFIFOLVL</b> register) and the <b>WRIM</b> bit in the <b>EPIIM</b> register is set, triggering an interrupt to the interrupt controller.
	0			The number of available entries in the WFIFO is above the range specified by the trigger level or the interrupt is masked.
1	RDMIS	R	0	Read Masked Interrupt Status
Value Description				
	1			The number of valid entries in the NBRFIFO is within the range specified by the trigger level (the <b>RDFIFO</b> field in the <b>EPIFIFOLVL</b> register) and the <b>RDIM</b> bit in the <b>EPIIM</b> register is set, triggering an interrupt to the interrupt controller.
	0			The number of valid entries in the NBRFIFO is below the range specified by the trigger level or the interrupt is masked.
0	ERRMIS	R	0	Error Masked Interrupt Status
Value Description				
	1			A WFIFO Full, a Read Stalled, or a Timeout error has occurred and the <b>ERIM</b> bit in the <b>EPIIM</b> register is set, triggering an interrupt to the interrupt controller.
	0			An error has not occurred or the interrupt is masked.

### Register 30: EPI Error Interrupt Status and Clear (EPIEISC), offset 0x21C

This register is used to clear a pending error interrupt. If any of these bits are set, the `ERRRIS` bit in the `EPIRIS` register is set, and an EPI controller error is sent to the interrupt controller if the `ERIM` bit in the `EPIIM` register is set. Clearing any defined bit has no effect; setting a bit clears the error source and the raw error returns to 0. Note that writing to this register and reading back immediately (pipelined by the processor) returns the old register contents. One cycle is needed between write and read.

## 11 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The Stellaris<sup>®</sup> General-Purpose Timer Module (GPTM) contains four GPTM blocks (Timer 0, Timer 1, Timer 2, and Timer 3). Each GPTM block provides two 16-bit timers/counters (referred to as Timer A and Timer B) that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger  $\mu$ DMA transfers.

In addition, timers can be used to trigger analog-to-digital conversions (ADC). The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Stellaris<sup>®</sup> microcontrollers. Other timer resources include the System Timer (SysTick) (see “System Timer (SysTick)” on page 69) and the PWM timer in the PWM module (see “PWM Timer” on page 885).

The General-Purpose Timers provide the following features:

- Count up or down
- 16- or 32-bit programmable one-shot timer
- 16- or 32-bit programmable periodic timer
- 16-bit general-purpose timer with an 8-bit prescaler
- 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- ADC event trigger
- User-enabled stalling when the controller asserts CPU Halt flag during debug (excluding RTC mode)
- 16-bit input-edge count- or time-capture modes
- 16-bit PWM mode with software-programmable output inversion of the PWM signal
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine.
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

### 11.1 Block Diagram

**Note:** In Figure 11-1 on page 389, the specific CCP pins available depend on the Stellaris<sup>®</sup> device. See Table 11-1 on page 389 for the available CCPs.

Figure 11-1. GPTM Module Block Diagram

Table 11-1. Available CCP Pins

Timer	16-Bit Up/Down Counter	Even CCP Pin	Odd CCP Pin
Timer 0	Timer A	CCP0	-
	Timer B	-	CCP1
Timer 1	Timer A	CCP2	-
	Timer B	-	CCP3
Timer 2	Timer A	CCP4	-
	Timer B	-	CCP5
Timer 3	Timer A	CCP6	-
	Timer B	-	CCP7

## 11.2 Functional Description

The main components of each GPTM block are two free-running 16-bit up/down counters (referred to as Timer A and Timer B), two 16-bit match registers, 2 16-bit shadow registers, and two 16-bit load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface.

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 401), the **GPTM Timer A Mode (GPTMTAMR)** register (see page 402), and the **GPTM Timer B Mode (GPTMTBMR)** register (see page 404). When in one of the 32-bit modes, the timer can only act as a 32-bit timer. However, when configured in 16-bit mode, the GPTM can have its two 16-bit timers configured in any combination of the 16-bit modes.

### 11.2.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters Timer A and Timer B are initialized to 0xFFFF, along with their corresponding load registers: the **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 417) and the **GPTM Timer B Interval Load (GPTMTBILR)** register (see page 418) and shadow registers: the **GPTM Timer A Value (GPTMTAV)** register (see page 425) and the **GPTM Timer B Value (GPTMTBV)** register (see page 426). The prescale counters are initialized to 0x00: the **GPTM Timer A Prescale (GPTMTAPR)** register (see page 421) and the **GPTM Timer B Prescale (GPTMTBPR)** register (see page 422).

### 11.2.2 32-Bit Timer Operating Modes

This section describes the three GPTM 32-bit timer modes (One-Shot, Periodic, and RTC) and their configuration.

The GPTM is placed into 32-bit mode by writing a 0 (One-Shot/Periodic 32-bit timer mode) or a 1 (RTC mode) to the **GPTM Configuration (GPTMCFG)** register. In both configurations, certain GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR)** register [15:0], see page 417
- **GPTM Timer B Interval Load (GPTMTBILR)** register [15:0], see page 418
- **GPTM Timer A (GPTMTAR)** register [15:0], see page 423
- **GPTM Timer B (GPTMTBR)** register [15:0], see page 424
- **GPTM Timer A Value (GPTMTAV)** register [15:0], see page 425
- **GPTM Timer B Value (GPTMTBV)** register [15:0], see page 426

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

```
GPTMTBILR[15:0]:GPTMTAILR[15:0]
```

Likewise, a read access to **GPTMTAR** returns the value:

```
GPTMTBR[15:0]:GPTMTAR[15:0]
```

A read access to **GPTMTAV** returns the value:

```
GPTMTBV[15:0]:GPTMTAV[15:0]
```

#### 11.2.2.1 32-Bit One-Shot/Periodic Timer Mode

In 32-bit one-shot and periodic timer modes, the concatenated versions of the Timer A and Timer B registers are configured as a 32-bit up or down counter. The selection of one-shot or periodic mode is determined by the value written to the **TAMR** field of the **GPTM Timer A Mode (GPTMTAMR)** register (see page 402), and there is no need to write to the **GPTM Timer B Mode (GPTMTBMR)** register.

When software sets the **TAEN** bit in the **GPTM Control (GPTMCTL)** register (see page 406), the timer begins counting up or down from its preloaded value. Alternatively, if the **TAWOT** bit is set in the **GPTMTAMR** register, once the **TAEN** bit is set, the timer waits for the trigger from the previous timer to begin counting. This mode allows the timer modules to be daisy chained such that a single

timer can initiate multiple timing events. Care must be taken not to set the `TAWOT` bit in the **GPTMTAMR** register of GP Timer Module 0.

Once the time-out event (0x0000.0000 when counting down, 0xFFFF.FFFF when counting up) is reached, the timer reloads its start value from the concatenated **GPTMTAILR** on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the `TAEN` bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting. If the `TnSNAPS` bit in the **GPTMTnMR** register is set, the actual free-running value of the timer at the time-out event is loaded into the **GPTMTAR** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry.

In addition to reloading the count value, the GPTM generates interrupts and triggers when it reaches the time-out event. The GPTM sets the `TATORIS` bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 411), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 415). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTIMR)** register (see page 409), the GPTM also sets the `TATOMIS` bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 413). By setting the `TAMIE` bit in the **GPTMTAMR** register, an interrupt can also be generated when the Timer A value equals the value loaded into the **GPTM Timer A Match (GPTMTAMATCH)** register. This interrupt has the same status, masking, and clearing functions as the time-out interrupt. The ADC trigger is enabled by setting the `TAOTE` bit in **GPTMCTL**. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 230.

If software reloads the **GPTMTAILR** register while the counter is running, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the `TASTALL` bit in the **GPTMCTL** register is asserted, the timer freezes counting until the signal is deasserted.

### 11.2.2.2 32-Bit Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as a 32-bit up-counter. When RTC mode is selected for the first time, the counter is loaded with a value of 0x0000.0001. All subsequent load values must be written to the **GPTM Timer A Match (GPTMTAMATCHR)** register (see page 419) by the controller.

The input clock on the `CCP0`, `CCP2`, or `CCP4` pin is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the 32-bit counter.

When software writes the `TAEN` bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x0000.0001. When the current count value matches the preloaded value in the **GPTMTAMATCHR** register, it rolls over to a value of 0x0000.0000 and continues counting until either a hardware reset, or it is disabled by software (clearing the `TAEN` bit). When a match occurs, the GPTM asserts the `RTCRES` bit in **GPTMRIS**. If the RTC interrupt is enabled in **GPTIMR**, the GPTM also sets the `RTCMIS` bit in **GPTMISR** and generates a controller interrupt. The status flags are cleared by writing the `RTCCINT` bit in **GPTMICR**.

In addition to generating interrupts, a  $\mu$ DMA trigger can be generated. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 230.

If the `TASTALL` and/or `TBSTALL` bits in the **GPTMCTL** register are set, the timer does not freeze if the `RTCEN` bit is set in **GPTMCTL**.

### 11.2.3 16-Bit Timer Operating Modes

The GPTM is placed into global 16-bit mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 401). This section describes each of the GPTM 16-bit modes of

operation. Timer A and Timer B have identical modes, so a single description is given using an *n* to reference both.

### 11.2.3.1 16-Bit One-Shot/Periodic Timer Mode

In 16-bit one-shot and periodic timer modes, the timer is configured as a 16-bit up or down-counter with an optional 8-bit prescaler that effectively extends the counting range of the timer to 24 bits. The selection of one-shot or periodic mode is determined by the value written to the *TnMR* field of the **GPTMTnMR** register. The optional prescaler is loaded into the **GPTM Timer n Prescale (GPTMTnPR)** register.

When software sets the *TnEN* bit in the **GPTMCTL** register, the timer begins counting up or down from its preloaded value. Alternatively, if the *TnWOT* bit is set in the **GPTMTnMR** register, once the *TnEN* bit is set, the timer waits for the external trigger to begin counting. This mode allows the timer modules to be daisy chained such that a single timer can initiate multiple timing events.

Once the time-out event (0x0000 when counting down, 0xFFFF when counting up) is reached, the timer reloads its start value from **GPTMTnILR** and **GPTMTnPR** on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the *TnEN* bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting. If the *TnSNAPS* bit in the **GPTMTnMR** register is set, the actual free-running value of the timer at the time-out event is loaded into the **GPTMTAR** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry.

In addition to reloading the count value, the timer generates interrupts and triggers when it reaches the time-out event. The GPTM sets the *TnTORIS* bit in the **GPTMRIS** register, and holds it until it is cleared by writing the **GPTMICR** register. If the time-out interrupt is enabled in **GPTIMR**, the GPTM also sets the *TnTOMIS* bit in **GPTMISR** and generates a controller interrupt. By setting the *TnMIE* bit in the **GPTMTnMR** register, an interrupt can also be generated when the timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCH)** register. This interrupt has the same status, masking, and clearing functions as the time-out interrupt. The ADC trigger is enabled by setting the *TnOTE* bit in the **GPTMCTL** register. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 230.

If software reloads the **GPTMTAILR** register while the counter is running, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the *TnSTALL* bit in the **GPTMCTL** register is enabled, the timer freezes counting until the signal is deasserted.

The following example shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume an 80-MHz clock with *Tc*=12.5 ns (clock period).

**Table 11-2. 16-Bit Timer With Prescaler Configurations**

Prescale	#Clock ( <i>Tc</i> ) <sup>a</sup>	Max Time	Units
00000000	1	0.8192	mS
00000001	2	1.6385	mS
00000010	3	2.4576	mS
-----	--	--	--
11111100	254	208.0768	mS
11111110	255	208.896	mS
11111111	256	209.7152	mS

a. *Tc* is the clock period.

### 11.2.3.2 16-Bit Input Edge-Count Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Count mode, the timer is configured as a 16-bit down-counter with an optional 8-bit prescaler that effectively extends the counting range of the timer to 24 bits. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the  $T_nCMR$  bit of the **GPTMTnMR** register must be set to 0. The type of edge that the timer counts is determined by the  $T_nEVENT$  fields of the **GPTMCTL** register. During initialization, the **GPTM Timer n Match (GPTMTnMATCHR)** register is configured so that the difference between the value in the **GPTMTnILR** register and the **GPTMTnMATCHR** register equals the number of edge events that must be counted. The optional prescaler is loaded into the **GPTM Timer n Prescale (GPTMTnPR)** register.

When software writes the  $T_nEN$  bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements the counter by 1 until the event count matches **GPTMTnMATCHR**. When the counts match, the GPTM asserts the  $C_nMRIS$  bit in the **GPTMRIS** register (and the  $C_nMMIS$  bit, if the interrupt is not masked).

In addition to generating interrupts, a  $\mu$ DMA trigger can be generated. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 230.

The counter is then reloaded using the value in **GPTMTnILR**, and stopped because the GPTM automatically clears the  $T_nEN$  bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until  $T_nEN$  is re-enabled by software. The **GPTMTnV** contains the free-running timer value and can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

Figure 11-2 on page 394 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMnILR** = 0x000A and the match value is set to **GPTMnMATCHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted since the timer automatically clears the  $T_nEN$  bit after the current count matches the value in the **GPTMnMR** register.

Figure 11-2. 16-Bit Input Edge-Count Mode Example

### 11.2.3.3 16-Bit Input Edge-Time Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Time mode, the timer is configured as a 16-bit free-running down-counter with an optional 8-bit prescaler that effectively extends the counting range of the timer to 24 bits. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** register (or 0xFFFF at reset). This mode allows for event capture of either rising or falling edges, but not both. The timer is placed into Edge-Time mode by setting the **TnCMR** bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the **TnEVENT** fields of the **GPTMCnTL** register. The optional prescaler is loaded into the **GPTM Timer n Prescale (GPTMTnPR)** register.

When software writes the **TnEN** bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current **Tn** counter value is captured in the **GPTMTnR** register and is available to be read by the controller. The GPTM then asserts the **CnERIS** bit (and the **CnEMIS** bit, if the interrupt is not masked). The **GPTMTnV** is the free-running value of the timer and can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

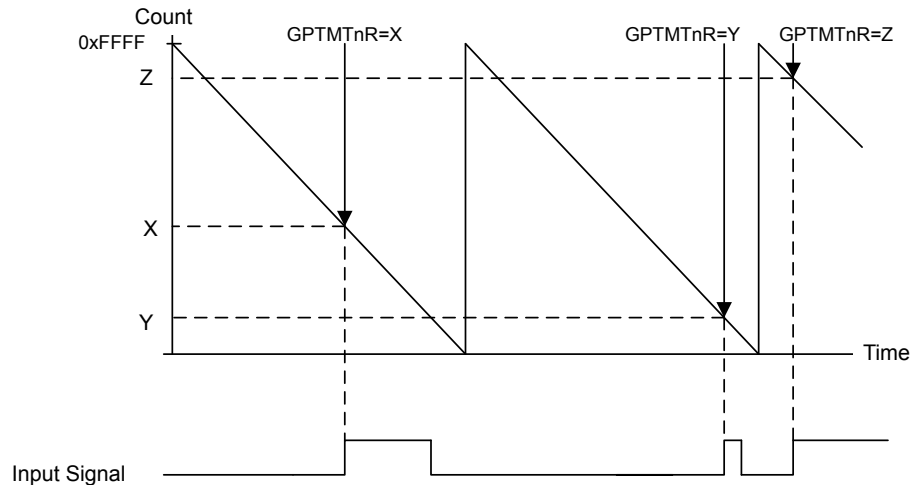

In addition to generating interrupts, a  $\mu$ DMA trigger can be generated. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel. See “Channel Configuration” on page 230.

After an event has been captured, the timer does not stop counting. It continues to count until the **TnEN** bit is cleared. When the timer reaches the 0x0000 state, it is reloaded with the value from the **GPTMnILR** register.

Figure 11-3 on page 395 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** register, and is held there until another rising edge is detected (at which point the new count value is loaded into **GPTMTnR**).

**Figure 11-3. 16-Bit Input Edge-Time Mode Example**

#### 11.2.3.4 16-Bit PWM Mode

**Note:** The prescaler is not available in 16-Bit PWM mode.

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a down-counter with a start value (and thus period) defined by **GPTMTnILR**. PWM mode is enabled with the **GPTMTnMR** register by setting the  $T_nAMS$  bit to 0x1, the  $T_nCMR$  bit to 0x0, and the  $T_nMR$  field to 0x2.

When software writes the  $T_nEN$  bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0000 state. On the next counter cycle, the counter reloads its start value from **GPTMTnILR** and continues counting until disabled by software clearing the  $T_nEN$  bit in the **GPTMCTL** register. No interrupts or status bits are asserted in PWM mode.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** register (its start state), and is deasserted when the counter value equals the value in the **GPTM Timer n Match Register (GPTMnMATCHR)**. Software has the capability of inverting the output PWM signal by setting the  $T_nPWML$  bit in the **GPTMCTL** register.

Figure 11-4 on page 396 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and  $T_nPWML = 0$  (duty cycle would be 33% for the  $T_nPWML = 1$  configuration). For this example, the start value is **GPTMnILR**=0xC350 and the match value is **GPTMnMR**=0x411A.

Figure 11-4. 16-Bit PWM Mode Example

### 11.2.4 DMA Operation

The timers each have a dedicated  $\mu$ DMA channel and can provide a request signal to the  $\mu$ DMA controller. The request signal is a burst type, and will occur whenever a timer raw interrupt condition occurs. The arbitration size of the  $\mu$ DMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the  $\mu$ DMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the  $\mu$ DMA controller will transfer 8 items, until all 256 items have been transferred.

No other special steps are needed to enable Timers for  $\mu$ DMA operation. Refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 226 for more details about programming the  $\mu$ DMA controller.

## 11.3 Initialization and Configuration

To use the general-purpose timers, the peripheral clock must be enabled by setting the `TIMER0`, `TIMER1`, `TIMER2`, and `TIMER3` bits in the `RCGC1` register. See page 167. If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the `RCGC2` register in the System Control module. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.

This section shows module initialization and configuration examples for each of the supported timer modes.

### 11.3.1 32-Bit One-Shot/Periodic Timer Mode

The GPTM is configured for 32-bit One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the `TAEN` bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0.
3. Configure the `TAMR` field in the **GPTM Timer A Mode Register (GPTMTAMR)**:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the `TASNAPS`, `TAWOT`, `TAMTE`, and `TACDIR` bits in the **GPTMTAMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down.
5. Load the start value into the **GPTM Timer A Interval Load Register (GPTMTAILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the `TAEN` bit in the **GPTMCTL** register to enable the timer and start counting.
8. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

In One-Shot mode, the timer stops counting after step 7 on page 397. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode does not stop counting after it times out.

### 11.3.2 32-Bit Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on its `CCP0`, `CCP2`, or `CCP4` pins. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the `TAEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x1.
3. Write the desired match value to the **GPTM Timer A Match Register (GPTMTAMATCHR)**.
4. Set/clear the `RTCEN` bit in the **GPTM Control Register (GPTMCTL)** as desired.
5. If interrupts are required, set the `RTCIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
6. Set the `TAEN` bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTAMATCHR** register, the counter is re-loaded with 0x0000.0000 and begins counting. If an interrupt is enabled, it does not have to be cleared.

### 11.3.3 16-Bit One-Shot/Periodic Timer Mode

A timer is configured for 16-bit One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x4.

3. Set the  $TnMR$  field in the **GPTM Timer Mode (GPTMTnMR)** register:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the  $TnSNAPS$ ,  $TnWOT$ ,  $TnMTE$  and  $TnCDIR$  bits in the **GPTMTnMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the start value into the **GPTM Timer Interval Load Register (GPTMTnILR)**.
7. If interrupts are required, set the appropriate bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
8. Set the  $TnEN$  bit in the **GPTM Control Register (GPTMCTL)** to enable the timer and start counting.
9. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

In One-Shot mode, the timer stops counting after step 8 on page 398. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode does not stop counting after it times out.

### 11.3.4 16-Bit Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the  $TnEN$  bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the  $TnCnMR$  field to 0x0 and the  $TnMR$  field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the  $TnEVENT$  field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. Load the desired event count into the **GPTM Timer n Match (GPTMTnMATCHR)** register.
8. If interrupts are required, set the  $CnMIM$  bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
9. Set the  $TnEN$  bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
10. Poll the  $CnMRIS$  bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the  $CnMCINT$  bit of the **GPTM Interrupt Clear (GPTMICR)** register.

In Input Edge-Count Mode, the timer stops after the desired number of edge events has been detected. To re-enable the timer, ensure that the  $TnEN$  bit is cleared and repeat step 4 on page 398 through step 9 on page 398.

### 11.3.5 16-Bit Input Edge Timing Mode

A timer is configured to Input Edge Timing mode by the following sequence:

1. Ensure the timer is disabled (the  $TnEN$  bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the  $TnCMR$  field to 0x1 and the  $TnMR$  field to 0x3.
4. Configure the type of event that the timer captures by writing the  $TnEVENT$  field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the  $CnEIM$  bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the  $TnEN$  bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the  $CnERIS$  bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the  $CnECINT$  bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register. The change takes effect at the next cycle after the write.

### 11.3.6 16-Bit PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the  $TnEN$  bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the  $TnAMS$  bit to 0x1, the  $TnCMR$  bit to 0x0, and the  $TnMR$  field to 0x2.
4. Configure the output state of the PWM signal (whether or not it is inverted) in the  $TnEVENT$  field of the **GPTM Control (GPTMCTL)** register.
5. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
6. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the desired value.
7. Set the  $TnEN$  bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Timing mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

## 11.4 Register Map

Table 11-3 on page 400 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- Timer0: 0x4003.0000
- Timer1: 0x4003.1000
- Timer2: 0x4003.2000
- Timer3: 0x4003.3000

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 167).

**Table 11-3. Timers Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	GPTMCFG	R/W	0x0000.0000	GPTM Configuration	401
0x004	GPTMTAMR	R/W	0x0000.0000	GPTM Timer A Mode	402
0x008	GPTMTBMR	R/W	0x0000.0000	GPTM Timer B Mode	404
0x00C	GPTMCTL	R/W	0x0000.0000	GPTM Control	406
0x018	GPTMIMR	R/W	0x0000.0000	GPTM Interrupt Mask	409
0x01C	GPTMRIS	RO	0x0000.0000	GPTM Raw Interrupt Status	411
0x020	GPTMMIS	RO	0x0000.0000	GPTM Masked Interrupt Status	413
0x024	GPTMICR	W1C	0x0000.0000	GPTM Interrupt Clear	415
0x028	GPTMTAILR	R/W	0xFFFF.FFFF	GPTM Timer A Interval Load	417
0x02C	GPTMTBILR	R/W	0x0000.FFFF	GPTM Timer B Interval Load	418
0x030	GPTMTAMATCHR	R/W	0xFFFF.FFFF	GPTM Timer A Match	419
0x034	GPTMTBMATCHR	R/W	0x0000.FFFF	GPTM Timer B Match	420
0x038	GPTMTAPR	R/W	0x0000.0000	GPTM Timer A Prescale	421
0x03C	GPTMTBPR	R/W	0x0000.0000	GPTM Timer B Prescale	422
0x048	GPTMTAR	RO	0xFFFF.FFFF	GPTM Timer A	423
0x04C	GPTMTBR	RO	0x0000.FFFF	GPTM Timer B	424
0x050	GPTMTAV	RO	0xFFFF.FFFF	GPTM Timer A Value	425
0x054	GPTMTBV	RO	0x0000.FFFF	GPTM Timer B Value	426

## 11.5 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

## Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

### GPTM Configuration (GPTMCFG)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000

31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	GPTMCFG	R/W	0x0	GPTM Configuration

The GPTMCFG values are defined as follows:

Value	Description
0x0	32-bit timer configuration.
0x1	32-bit real-time clock (RTC) counter configuration.
0x2-0x3	Reserved
0x4-0x7	16-bit timer configuration, function is controlled by bits 1:0 of <b>GPTMTAMR</b> and <b>GPTMTBMR</b> .

## Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the **TAAMS** bit to 0x1, the **TACMR** bit to 0x0, and the **TAMR** field to 0x2.

In 16-bit timer configuration, **TAMR** controls the 16-bit timer modes for Timer A. In 32-bit timer configuration, this register controls the mode, and the contents of **GPTMTBMR** are ignored.

### GPTM Timer A Mode (GPTMTAMR)

Timer0 base: 0x4003.0000

31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	TASNAPS	R/W	0	GPTM Timer A Snap-Shot Mode  Value Description 0 Snap-shot mode is disabled. 1 If Timer A is configured in the periodic mode, the actual free-running value of Timer A is loaded at the time-out event into the <b>GPTM Timer A (GPTMTAR)</b> register.
6	TAWOT	R/W	0	GPTM Timer A Wait-on-Trigger  Value Description 0 Timer A begins counting as soon as it is enabled. 1 If Timer A is enabled ( <b>TAEN</b> is set in the <b>GPTMCTL</b> register), Timer A does not begin counting until it receives a trigger from the timer in the previous position in the daisy chain. This function is valid for both one-shot and periodic modes.  This bit must be clear for GP Timer Module 0, Timer A.

Bit/Field	Name	Type	Reset	Description
5	TAMIE	R/W	0	<p>GPTM Timer A Match Interrupt Enable</p> <p>Value Description</p> <p>0 The match interrupt is disabled.</p> <p>1 An interrupt is generated when the match value in the <b>GPTMTAMATCHR</b> register is reached in the one-shot and periodic modes.</p>
4	TACDIR	R/W	0	<p>GPTM Timer A Count Direction</p> <p>Value Description</p> <p>0 The timer counts down.</p> <p>1 When in one-shot or periodic mode, the timer counts up. When counting up, the timer starts from a value of 0x0000.</p>
3	TAAMS	R/W	0	<p>GPTM Timer A Alternate Mode Select</p> <p>The <b>TAAMS</b> values are defined as follows:</p> <p>Value Description</p> <p>0 Capture mode is enabled.</p> <p>1 PWM mode is enabled.</p> <p><b>Note:</b> To enable PWM mode, you must also clear the <b>TACMR</b> bit and set the <b>TAMR</b> field to 0x2.</p>
2	TACMR	R/W	0	<p>GPTM Timer A Capture Mode</p> <p>The <b>TACMR</b> values are defined as follows:</p> <p>Value Description</p> <p>0 Edge-Count mode</p> <p>1 Edge-Time mode</p>
1:0	TAMR	R/W	0x0	<p>GPTM Timer A Mode</p> <p>The <b>TAMR</b> values are defined as follows:</p> <p>Value Description</p> <p>0x0 Reserved</p> <p>0x1 One-Shot Timer mode</p> <p>0x2 Periodic Timer mode</p> <p>0x3 Capture mode</p> <p>The Timer mode is based on the timer configuration defined by bits 2:0 in the <b>GPTMCFG</b> register (16-or 32-bit).</p>

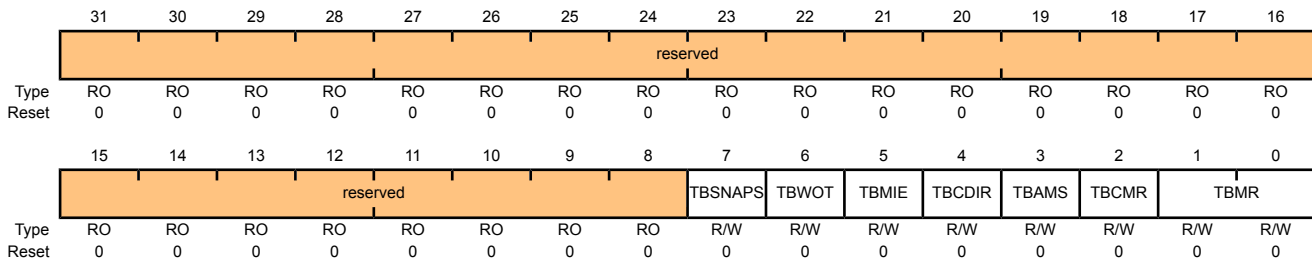

### Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the **TBAMS** bit to 0x1, the **TBCMR** bit to 0x0, and the **TBMR** field to 0x2.

In 16-bit timer configuration, these bits control the 16-bit timer modes for Timer B. In 32-bit timer configuration, this register's contents are ignored, and **GPTMTAMR** is used.

#### GPTM Timer B Mode (GPTMTBMR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000

### Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

## Register 7: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

## Register 8: GPTM Interrupt Clear (GPTMICR), offset 0x024

This register is used to clear the status bits in the **GPTMRIS** and **GPTMMIS** registers. Writing a 1 to a bit clears the corresponding bit in the **GPTMRIS** and **GPTMMIS** registers.

### GPTM Interrupt Clear (GPTMICR)

## Register 9: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028

This register is used to load the starting count value into the timer. When GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

### GPTM Timer A Interval Load (GPTMTAILR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x028  
 Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	TAILRH	R/W	0xFFFF	GPTM Timer A Interval Load Register High  When configured for 32-bit mode via the <b>GPTMCFG</b> register, the <b>GPTM Timer B Interval Load (GPTMTBILR)</b> register loads this value on a write. A read returns the current value of <b>GPTMTBILR</b> .  In 16-bit mode, this field reads as 0 and does not have an effect on the state of <b>GPTMTBILR</b> .
15:0	TAILRL	R/W	0xFFFF	GPTM Timer A Interval Load Register Low  For both 16- and 32-bit modes, writing this field loads the counter for Timer A. A read returns the current value of <b>GPTMTAILR</b> .

### Register 10: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C

This register is used to load the starting count value into Timer B. When the GPTM is configured to a 32-bit mode, **GPTMTBILR** returns the current value of Timer B and ignores writes.

#### GPTM Timer B Interval Load (GPTMTBILR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x02C  
 Type R/W, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TBILRL	R/W	0xFFFF	GPTM Timer B Interval Load Register

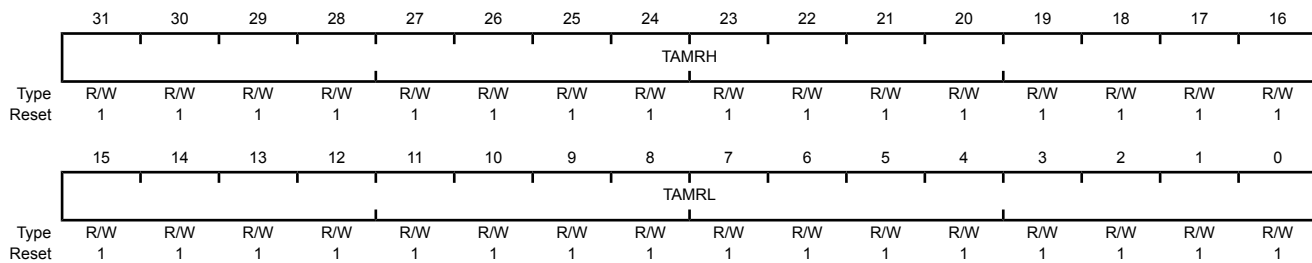

When the GPTM is not configured as a 32-bit timer, a write to this field updates **GPTMTBILR**. In 32-bit mode, writes are ignored, and reads return the current value of **GPTMTBILR**.

## Register 11: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode. In 16-bit Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value.

### GPTM Timer A Match (GPTMTAMATCHR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x030  
 Type R/W, reset 0xFFFF.FFFF

15:0	TAMRL	R/W	0xFFFF	<p>GPTM Timer A Match Register Low</p> <p>When the timer is configured for 32-bit mode via the <b>GPTMCFG</b> register, this value is compared to the lower half of <b>GPTMTAR</b>, to determine match events.</p> <p>When the timer is configured for 16-bit mode via the <b>GPTMCFG</b> register, this value is compared to <b>GPTMTAR</b> to determine match events.</p> <p>When configured for 16-bit mode, this value along with <b>GPTMTAILR</b>, determines how many edge events are counted. The total number of edge events counted is equal to the value in <b>GPTMTAILR</b> minus this value.</p> <p>When configured for PWM mode, this value along with <b>GPTMTAILR</b>, determines the duty cycle of the output PWM signal.</p>

### Register 12: GPTM Timer B Match (GPTMTBMATCHR), offset 0x034

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode. In 16-bit Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value.

#### GPTM Timer B Match (GPTMTBMATCHR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x034  
 Type R/W, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TBMRL	R/W	0xFFFF	GPTM Timer B Match Register Low  When the timer is configured for 16-bit mode via the <b>GPTMCFG</b> register, this value is compared to <b>GPTMTBR</b> to determine match events.  When configured for 16-bit mode, this value along with <b>GPTMTBILR</b> , determines how many edge events are counted. The total number of edge events counted is equal to the value in <b>GPTMTBILR</b> minus this value.  When configured for PWM mode, this value along with <b>GPTMTBILR</b> , determines the duty cycle of the output PWM signal.

## Register 13: GPTM Timer A Prescale (GPTMTAPR), offset 0x038

This register allows software to extend the range of the 16-bit timers.

### GPTM Timer A Prescale (GPTMTAPR)

Timer0 base: 0x4003.0000  
 Timer1 base: 0x4003.1000  
 Timer2 base: 0x4003.2000  
 Timer3 base: 0x4003.3000  
 Offset 0x038  
 Type R/W, reset 0x0000.0000

15:0	TBVL	RO	0xFFFF	GPTM Timer B Register A read returns the current value of Timer B.

## 12 Watchdog Timer

A watchdog timer can generate nonmaskable interrupts (NMIs) or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The LM3S9792 microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other is clocked by the PIOSC (Watchdog Timer 1). The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

The Stellaris<sup>®</sup> Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the controller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

## 12.1 Block Diagram

Figure 12-1. WDT Module Block Diagram

## 12.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the `RESEN` bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

### 12.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The **WRC** bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for **WRC=1** prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

## 12.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the **WDT** bit in the **RCGC0** register. See page 158.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
3. If the Watchdog is configured to trigger system resets, set the **RESEN** bit in the **WDTCTL** register.
4. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
5. Set the **INTEN** bit in the **WDTCTL** register to enable the Watchdog and lock the control register.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

## 12.4 Register Map

Table 12-1 on page 430 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 158).

**Table 12-1. Watchdog Timer Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	WDTLOAD	R/W	0xFFFF.FFFF	Watchdog Load	431
0x004	WDTVALUE	RO	0xFFFF.FFFF	Watchdog Value	432
0x008	WDTCTL	R/W	0x0000.0000 for WDT0, 0x8000.0000 for WDT1	Watchdog Control	433

## 12.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

## Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

### Watchdog Load (WDTLOAD)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x000

Type R/W, reset 0xFFFF.FFFF

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WDTLOAD															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WDTLOAD															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit/Field	Name	Type	Reset	Description
31:0	WDTLOAD	R/W	0xFFFF.FFFF	Watchdog Load Value

## Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

### Watchdog Value (WDTVALUE)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x004

Type RO, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	WDTVALUE	RO	0xFFFF.FFFF	Watchdog Value Current value of the 32-bit down counter.

### Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled, all subsequent writes to the control register are ignored. The only mechanism that can re-enable writes is a hardware reset.

**Important:** Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The `WRC` bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for `WRC=1` prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a `WRC` bit.

#### Watchdog Control (WDTCTL)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x008

Type R/W, reset 0x0000.0000 for WDT0, 0x8000.0000 for WDT1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31	WRC	RO	1	Write Complete
----	-----	----	---	----------------

The `WRC` values are defined as follows:

Value	Description
-------	-------------

0	A write access to one of the WDT1 registers is in progress.
---	---

1	The write access has completed, and WDT1 registers can be read or written.
---	--

**Note:** This bit is reserved for WDT0 and has a reset value of 0.

30:2	reserved	RO	0x000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
------	----------	----	-----------	---

Bit/Field	Name	Type	Reset	Description
1	RESEN	R/W	0	Watchdog Reset Enable The RESEN values are defined as follows:  Value Description 0 Disabled. 1 Enable the Watchdog module reset output.
0	INTEN	R/W	0	Watchdog Interrupt Enable The INTEN values are defined as follows:  Value Description 0 Interrupt event disabled (once this bit is set, it can only be cleared by a hardware reset). 1 Interrupt event enabled. Once enabled, all writes are ignored.

## Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Value for a read or reset is indeterminate.

### Watchdog Interrupt Clear (WDTICR)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x00C

Type WO, reset -

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved							STALL	reserved							
Type	RO	RO	RO	RO	RO	RO	RO	R/W	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	STALL	R/W	0	Watchdog Stall Enable  When set to 1, if the Stellaris® microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting.
7:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

### Watchdog Lock (WDTLOCK)

WDT0 base: 0x4000.0000  
 WDT1 base: 0x4000.1000  
 Offset 0xC00  
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WDTLOCK															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WDTLOCK															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	WDTLOCK	R/W	0x0000	Watchdog Lock

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates.

A read of this register returns the following values:

Value	Description
0x0000.0001	Locked
0x0000.0000	Unlocked

### Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

#### Watchdog Peripheral Identification 4 (WDTPeriphID4)

WDT0 base: 0x4000.0000  
 WDT1 base: 0x4000.1000  
 Offset 0xFD0  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

## 13 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter units are included, which share sixteen input channels. The two converter units may be sampled in the same processor clock or out of phase with each other.

The Stellaris<sup>®</sup> ADC module features 10-bit conversion resolution and supports sixteen input channels, plus an internal temperature sensor. The ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. A digital comparator function is included which allows the conversion value to be diverted to a digital comparator module. The digital comparator module provides digital comparator. The comparator module measures the ADC conversion value against two user-defined values to determine the operational range of the signal.

The Stellaris<sup>®</sup> ADC module provides the following features:

- Sixteen analog input channels
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Sample rate of one million samples/second
- Flexible, configurable analog-to-digital conversion
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples for improved accuracy
- Digital comparison unit providing digital comparator
- Converter uses an internal 3-V reference or an external reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each sample sequencer
  - Burst request asserted when interrupt is triggered

## 13.1 Block Diagram

The Stellaris<sup>®</sup> microcontroller contains two identical Analog-to-Digital Converter units. These two modules, ADC0 and ADC1, share the same sixteen analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 13-1 on page 453 shows how the two modules are connected to analog inputs and the system bus.

Figure 13-1. Implementation of Two ADC Blocks

Figure 13-2 on page 453 provides details on the internal configuration of the ADC controls and data registers.

Figure 13-2. ADC Module Block Diagram

## 13.2 Functional Description

The Stellaris<sup>®</sup> ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. The  $\mu$ DMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

### 13.2.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 13-1 on page 454 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. In this implementation, each FIFO entry is a 32-bit word, with the lower 10 bits containing the conversion result.

**Table 13-1. Samples and FIFO Depth of Sequencers**

Sequencer	Number of Samples	Depth of FIFO
SS3	1	1
SS2	4	4
SS1	4	4
SS0	8	8

For a given sample sequence, each sample is defined by two 4-bit nibbles in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** nibbles select the input pin, while the **ADCSSCTLn** nibbles contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SSn** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 484.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence is allowed. In the **ADCSSCTLn** register, the **IE<sub>n</sub>** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO<sub>n</sub>)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTAT<sub>n</sub>)** registers along with **FULL** and **EMPTY** status flags. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

## 13.2.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- Sequence prioritization
- Trigger configuration
- Comparator configuration

Most of the ADC control logic runs at the ADC clock rate of 14-18 MHz. The internal ADC divider is configured automatically by hardware when the system XTAL is selected. The automatic clock divider configuration targets 16.667 MHz operation for all Stellaris® devices.

### 13.2.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the MASK bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the ADCIM register. Sequencer interrupts are cleared by writing a 1 to the corresponding IN bit in ADCISC. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

### 13.2.2.2 DMA Operation

The ADC module provides a request signal to the  $\mu$ DMA controller for each sample sequencer. Each sample sequencer has a dedicated  $\mu$ DMA channel. The request signal is a burst type and is asserted whenever an interrupt is enabled in a sample sequence (IE bit in the **ADCSSCTLn** register is set). Single requests are not supported.

The arbitration size of the  $\mu$ DMA transfer must be a power of 2, and the associated IE bits in the **ADDSSCTLn** register must be set. For example, if the  $\mu$ DMA channel of SS0 has an arbitration size of four, the IE3 bit (4th sample) and the IE7 bit (8th sample) must be set. Thus the  $\mu$ DMA request occurs every time 4 samples have been acquired. No other special steps are needed to enable the ADC module for  $\mu$ DMA operation.

Refer to the "Micro Direct Memory Access ( $\mu$ DMA)" on page 226 for more details about programming the  $\mu$ DMA controller.

### 13.2.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

### 13.2.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on GPIO PB4, a GP Timer, PWM2, and continuous sampling.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers.

#### 13.2.2.5 External Voltage Reference

An external reference voltage may be provided to serve as the maximum conversion value reference. The  $V_{REF}$  bit in the **ADC Control (ADCCTL)** register specifies whether to use the internal or external reference. The useful range for the external voltage reference is  $2.4\text{ V} - V_{DDA}$ . Ground is always used as the reference level for the minimum conversion value. Care must be taken to supply a reference voltage of acceptable quality.

#### 13.2.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 486). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

#### 13.2.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 10-bit, low-power, high-precision conversion value. The successive-approximation algorithm uses a current mode D/A converter to achieve lower settling time, resulting in higher conversion speeds for the A/D converter. In addition, built-in sample-and-hold circuitry with offset-calibration circuitry improves conversion accuracy. The sample-and-hold circuitry is open for the first time period of a conversion as specified by  $T_{ADCCA}$  and requires that the ADC be run from the PLL or a 16-MHz clock source.

The ADC operates from the 3.3-V analog and 1.2-V digital power supply. Integrated shutdown modes are available to reduce power consumption when ADC conversions are not required. The analog inputs are connected to the ADC through custom pads and specially balanced input paths to minimize the distortion on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in "Analog-to-Digital Converter" on page 1012.

##### 13.2.4.1 Internal Voltage Reference

The band-gap circuitry generates an internal 3.0 V reference that can be used by the ADC to produce a conversion value from the selected analog input. The range of this conversion value is from 0x000 to 0x3FF. In single-ended-input mode, the 0x000 value corresponds to an analog input voltage of 0.0 V; the 0x3FF value corresponds to an analog input voltage of 3.0 V. This configuration results in a resolution of approximately 2.9 mV per ADC code. While the analog input pads can handle voltages beyond this range, the ADC conversions saturate in under-voltage and over-voltage cases. Figure 13-3 on page 457 shows the ADC conversion function of the analog inputs.

Figure 13-3. Internal Voltage Conversion Result

#### 13.2.4.2 External Voltage Reference

The ADC can use an external voltage reference to produce the conversion value from the selected analog input by setting the  $V_{REF}$  bit in the **ADC Control (ADCCTL)** register. While the range of the conversion value remains the same (0x000 to 0x3FF), the analog voltage associated with the 0x3FF value corresponds to the value of the external voltage reference, resulting in a smaller voltage resolution per ADC code. Analog input voltages above the external voltage reference saturate to 0x3FF while those below 0.0 V continue to saturate at 0x000. Figure 13-4 on page 458 shows the ADC conversion function of the analog inputs when using an external voltage reference.

Figure 13-4. External Voltage Conversion Result

The external voltage reference can be useful in circuits where the maximum analog input voltage is significantly lower than 3.0 V (3.3 V). In this case, the maximum value of the analog input can be used as the external voltage reference. The result is conversions covering the entire 10-bit range and a smaller voltage resolution per bit. There is a physical limit to how far the external voltage reference can be lowered before the quantization resolution of the ADC is exceeded and accuracy starts to be affected. “Analog-to-Digital Converter” on page 1012 provides detailed information on the tradeoffs between voltage reference and conversion accuracy.

### 13.2.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the  $D_n$  bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential pair 1 samples analog inputs 2 and 3; and so on (see Table 13-2 on page 458). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

Table 13-2. Differential Sampling Pairs

Differential Pair	Analog Inputs
0	0 and 1
1	2 and 3
2	4 and 5
3	6 and 7
4	8 and 9

Differential Pair	Analog Inputs
5	10 and 11
6	12 and 13
7	14 and 15

The voltage sampled in differential mode is the difference between the odd and even channels:

$\Delta V$  (differential voltage) =  $V_{IN\_EVEN}$  (even channels) –  $V_{IN\_ODD}$  (odd channels), therefore:

- If  $\Delta V = 0$ , then the conversion result = 0x1FF
- If  $\Delta V > 0$ , then the conversion result > 0x1FF (range is 0x1FF–0x3FF)
- If  $\Delta V < 0$ , then the conversion result < 0x1FF (range is 0–0x1FF)

The differential pairs assign polarities to the analog inputs: the even-numbered input is always positive, and the odd-numbered input is always negative. In order for a valid conversion result to appear, the negative input must be in the range of  $\pm 1.5$  V of the positive input. If an analog input is greater than 3 V or less than 0 V (the valid range for analog inputs), the input voltage is clipped, meaning it appears as either 3 V or 0 V, respectively, to the ADC.

Figure 13-5 on page 459 shows an example of the negative input centered at 1.5 V. In this configuration, the differential range spans from -1.5 V to 1.5 V. Figure 13-6 on page 460 shows an example where the negative input is centered at -0.75 V, meaning inputs on the positive input saturate past a differential voltage of -0.75 V since the input voltage is less than 0 V. Figure 13-7 on page 460 shows an example of the negative input centered at 2.25 V, where inputs on the positive channel saturate past a differential voltage of 0.75 V since the input voltage would be greater than 3 V.

**Figure 13-5. Differential Sampling Range,  $V_{IN\_ODD} = 1.5$  V**

Figure 13-6. Differential Sampling Range,  $V_{IN\_ODD} = 0.75\text{ V}$

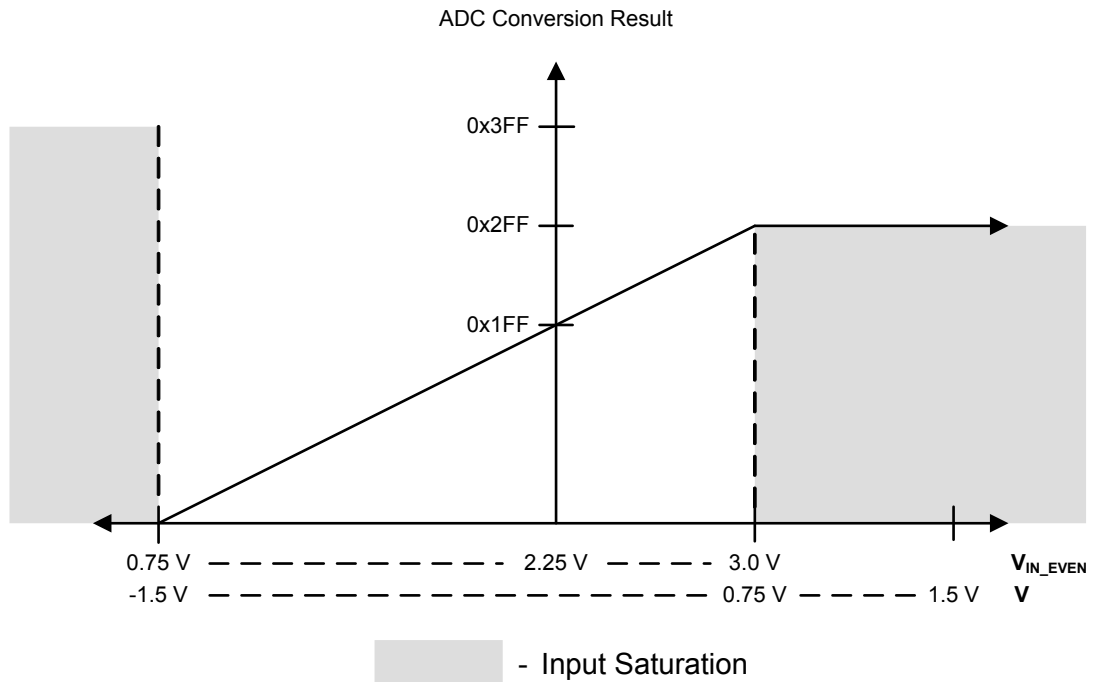

Figure 13-7. Differential Sampling Range,  $V_{IN\_ODD} = 2.25\text{ V}$

### 13.2.6 Internal Temperature Sensor

The temperature sensor's primary purpose is to notify the system that the internal temperature is too high or low for reliable operation.

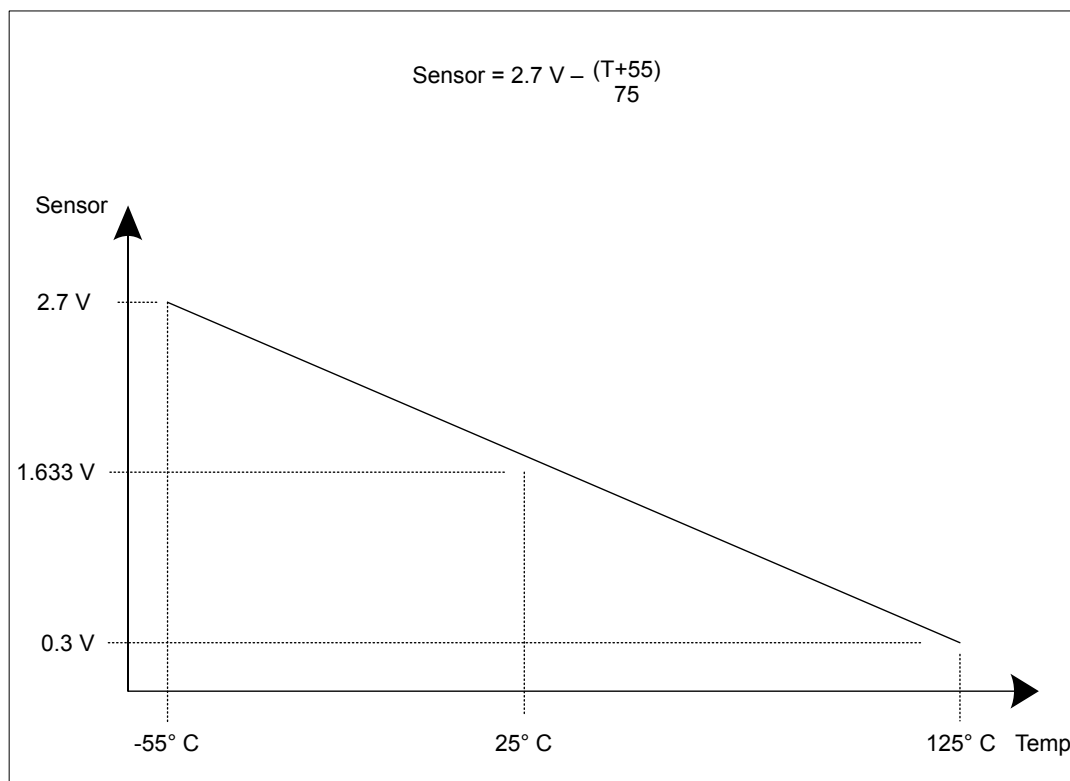

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC.

The internal temperature sensor provides an analog temperature reading as well as a reference voltage. The voltage at the output terminal SENSO is given by the following equation:

$$SENSO = 2.7 - ((T + 55) / 75)$$

This relation is shown in Figure 13-8 on page 461.

**Figure 13-8. Internal Temperature Sensor Characteristic**

### 13.2.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor overhead that is required, atwothreefourfivesixseveneight dual-level value digital comparators are provided. Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCMPn)** registers. If the observed signal moves out of the acceptable range, a processor interrupt can be generated and/or a trigger can be sent to the PWM module. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be applied to three separate regions (low band, mid band, high band) as defined by the user.

### 13.2.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the  $S_nDCOP$  bits in the **ADC Sample Sequence n Operation (ADCSSOPn)** register. These selected ADC conversions are used by their respective digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion data is used by each function to determine if the right conditions have been met to assert the associated output.

#### *Interrupts*

The digital comparator interrupt function is enabled by setting the  $CIE$  bit in the **ADC Digital Comparator Control (ADCDCCTLn)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the  $DCONSS_x$  bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

#### *Triggers*

The digital comparator trigger function is enabled by setting the  $CTE$  bit in the **ADCDCCTLn** register. This bit enables the trigger function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, the corresponding digital comparator trigger to the PWM module is asserted.

### 13.2.7.2 Operational Modes

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the  $CIM$  or  $CTM$  field in the **ADCDCCTLn** register.

#### *Always Mode*

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

#### *Once Mode*

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

#### *Hysteresis-Always Mode*

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

**Hysteresis-Once Mode**

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

**13.2.7.3 Function Ranges**

The two comparison values, COMP0 and COMP1, in the **ADC Digital Comparator Range (ADCDCMPn)** register effectively break the conversion area into three distinct regions. These regions are referred to as the low-band (less than or equal to COMP0), mid-band (greater than COMP0 but less than or equal to COMP1), and high-band (greater than COMP1) regions. COMP0 and COMP1 may be programmed to the same value, effectively creating two regions, but COMP1 must always be greater than or equal to the value of COMP0. A COMP1 value that is less than COMP0 generates unpredictable results.

**Low-Band Operation**

To operate in the low-band region, either the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x0. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 13-9 on page 463. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

**Figure 13-9. Low-Band Operation (CIC=0x0 and/or CTC=0x0)**

**Mid-Band Operation**

To operate in the mid-band region, either the `CIC` field or the `CTC` field in the `ADCDCCTLn` register must be programmed to `0x1`. This setting causes interrupts or triggers to be generated in the mid-band region according the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 13-10 on page 464. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

**Figure 13-10. Mid-Band Operation (CIC=0x1 and/or CTC=0x1)**

**High-Band Operation**

To operate in the high-band region, either the `CIC` field or the `CTC` field in the `ADCDCCTLn` register must be programmed to `0x3`. This setting causes interrupts or triggers to be generated in the high-band region according the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 13-11 on page 465. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is de-asserted and a "1" indicates that the signal is asserted.

Figure 13-11. High-Band Operation (CIC=0x3 and/or CTC=0x3)

### 13.3 Initialization and Configuration

In order for the ADC module to be used, the PLL must be enabled and programmed to a supported crystal frequency in the **RCC** register (see page 113). Using unsupported frequencies can cause faulty operation in the ADC module.

#### 13.3.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock by writing a value of 0x0001.0000 to the **RCGC0** register (see page 158).
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register (see page 179). To find out which GPIO port to enable, refer to Table 25-5 on page 990.
3. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 326) in the associated GPIO block.
4. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

#### 13.3.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

1. Ensure that the sample sequencer is disabled by clearing the corresponding `ASENn` bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
3. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUX<sub>n</sub>** register.
4. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTL<sub>n</sub>** register. When programming the last nibble, ensure that the `END` bit is set. Failure to set the `END` bit causes unpredictable behavior.
5. If interrupts are to be used, set the corresponding `MASK` bit in the **ADCIM** register.
6. Enable the sample sequencer logic by setting the corresponding `ASENn` bit in the **ADCACTSS** register.

## 13.4 Register Map

Table 13-3 on page 466 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 158).

**Table 13-3. ADC Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	ADCACTSS	R/W	0x0000.0000	ADC Active Sample Sequencer	469
0x004	ADCRIS	RO	0x0000.0000	ADC Raw Interrupt Status	470

### 13.5 Register Descriptions

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

## Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

### ADC Active Sample Sequencer (ADCACTSS)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x000

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	Reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	Reserved												ASEN3	ASEN2	ASEN1	ASEN0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	Reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ASEN3	R/W	0	ADC SS3 Enable When set, this bit enables Sample Sequencer 3. When clear, this bit disables Sample Sequencer 3.
2	ASEN2	R/W	0	ADC SS2 Enable When set, this bit enables Sample Sequencer 2. When clear, this bit disables Sample Sequencer 2.
1	ASEN1	R/W	0	ADC SS1 Enable When set, this bit enables Sample Sequencer 1. When clear, this bit disables Sample Sequencer 1.
0	ASEN0	R/W	0	ADC SS0 Enable When set, this bit enables Sample Sequencer 0. When clear, this bit disables Sample Sequencer 0.

## Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

### ADC Raw Interrupt Status (ADCRIS)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x004  
 Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Reserved															INRDC
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Reserved												INR3	INR2	INR1	INR0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:17	Reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	INRDC	RO	0	Digital Comparator Raw Interrupt Status  This bit is set when at least one bit in the <b>ADCDCISC</b> register is set, meaning that a digital comparator interrupt has occurred.  This bit is clear when all bits in the <b>ADCDCISC</b> register are clear.
15:4	Reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	INR3	RO	0	SS3 Raw Interrupt Status  This bit is set when a sample has completed conversion and the respective <b>ADCSSCTL3 IEn</b> bit is set, enabling a raw interrupt.  This bit is cleared by writing a 1 to the <b>IN3</b> bit in the <b>ADCISC</b> register.
2	INR2	RO	0	SS2 Raw Interrupt Status  This bit is set when a sample has completed conversion and the respective <b>ADCSSCTL2 IEn</b> bit is set, enabling a raw interrupt.  This bit is cleared by writing a 1 to the <b>IN2</b> bit in the <b>ADCISC</b> register.
1	INR1	RO	0	SS1 Raw Interrupt Status  This bit is set when a sample has completed conversion and the respective <b>ADCSSCTL1 IEn</b> bit is set, enabling a raw interrupt.  This bit is cleared by writing a 1 to the <b>IN1</b> bit in the <b>ADCISC</b> register.

Bit/Field	Name	Type	Reset	Description
0	INR0	RO	0	<p>SS0 Raw Interrupt Status</p> <p>This bit is set when a sample has completed conversion and the respective <b>ADCSSCTL0</b> <i>IE<sub>n</sub></i> bit is set, enabling a raw interrupt.</p> <p>This bit is cleared by writing a 1 to the <i>IN0</i> bit in the <b>ADCISC</b> register.</p>

### Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently. Only a single DCONSS<sub>n</sub> bit should be set at any given time. Setting more than one of these bits results in the INRDC bit from the ADCRIS register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines.

#### ADC Interrupt Mask (ADCIM)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x008  
 Type R/W, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:20	Reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	DCONSS3	R/W	0	Digital Comparator Interrupt on SS3  When this bit is set, the raw interrupt signal from the digital comparators (INRDC bit in the ADCRIS register) is sent to the interrupt controller on the SS3 interrupt line.  When this bit is clear, the status of the digital comparators does not affect the SS3 interrupt status.
18	DCONSS2	R/W	0	Digital Comparator Interrupt on SS2  When this bit is set, the raw interrupt signal from the digital comparators (INRDC bit in the ADCRIS register) is sent to the interrupt controller on the SS2 interrupt line.  When this bit is clear, the status of the digital comparators does not affect the SS2 interrupt status.
17	DCONSS1	R/W	0	Digital Comparator Interrupt on SS1  When this bit is set, the raw interrupt signal from the digital comparators (INRDC bit in the ADCRIS register) is sent to the interrupt controller on the SS1 interrupt line.  When this bit is clear, the status of the digital comparators does not affect the SS1 interrupt status.

Bit/Field	Name	Type	Reset	Description
16	DCONSS0	R/W	0	<p>Digital Comparator Interrupt on SS0</p> <p>When this bit is set, the raw interrupt signal from the digital comparators (<b>INRDC</b> bit in the <b>ADCRIS</b> register) is sent to the interrupt controller on the SS0 interrupt line.</p> <p>When this bit is clear, the status of the digital comparators does not affect the SS0 interrupt status.</p>
15:4	Reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	MASK3	R/W	0	<p>SS3 Interrupt Mask</p> <p>When this bit is set, the raw interrupt signal from Sample Sequencer 3 (<b>ADCRIS</b> register <b>INR3</b> bit) is sent to the interrupt controller.</p> <p>When this bit is clear, the status of Sample Sequencer 3 does not affect the SS3 interrupt status.</p>
2	MASK2	R/W	0	<p>SS2 Interrupt Mask</p> <p>When this bit is set, the raw interrupt signal from Sample Sequencer 2 (<b>ADCRIS</b> register <b>INR2</b> bit) is sent to the interrupt controller.</p> <p>When this bit is clear, the status of Sample Sequencer 2 does not affect the SS2 interrupt status.</p>
1	MASK1	R/W	0	<p>SS1 Interrupt Mask</p> <p>When this bit is set, the raw interrupt signal from Sample Sequencer 1 (<b>ADCRIS</b> register <b>INR1</b> bit) is sent to the interrupt controller.</p> <p>When this bit is clear, the status of Sample Sequencer 1 does not affect the SS1 interrupt status.</p>
0	MASK0	R/W	0	<p>SS0 Interrupt Mask</p> <p>When this bit is set, the raw interrupt signal from Sample Sequencer 0 (<b>ADCRIS</b> register <b>INR0</b> bit) is sent to the interrupt controller.</p> <p>When this bit is clear, the status of Sample Sequencer 0 does not affect the SS0 interrupt status.</p>

### Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective **INR** and **MASK** bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence **INR<sub>n</sub>** bits are still cleared via the **ADCISC** register, even if the **IN<sub>n</sub>** bit is not set.

#### ADC Interrupt Status and Clear (ADCISC)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x00C  
 Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Reserved												DCINSS3	DCINSS2	DCINSS1	DCINSS0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:20	Reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	DCINSS3	RO	0	Digital Comparator Interrupt Status on SS3  This bit is set when both the <b>INRDC</b> bit in the <b>ADCRIS</b> register and the <b>DCONSS3</b> bit in the <b>ADCIM</b> register are set, providing a level-base interrupt to the interrupt controller.  This bit is cleared by writing a 1 to the appropriate location in the <b>ADCDCISC</b> register. Clearing the <b>ADCDCISC</b> register clears the <b>INRDC</b> bit.
18	DCINSS2	RO	0	Digital Comparator Interrupt Status on SS2  This bit is set when both the <b>INRDC</b> bit in the <b>ADCRIS</b> register and the <b>DCONSS2</b> bit in the <b>ADCIM</b> register are set, providing a level-base interrupt to the interrupt controller.  This bit is cleared by writing a 1 to the appropriate location in the <b>ADCDCISC</b> register. Clearing the <b>ADCDCISC</b> register clears the <b>INRDC</b> bit.
17	DCINSS1	RO	0	Digital Comparator Interrupt Status on SS1  This bit is set when both the <b>INRDC</b> bit in the <b>ADCRIS</b> register and the <b>DCONSS1</b> bit in the <b>ADCIM</b> register are set, providing a level-base interrupt to the interrupt controller.  This bit is cleared by writing a 1 to the appropriate location in the <b>ADCDCISC</b> register. Clearing the <b>ADCDCISC</b> register clears the <b>INRDC</b> bit.

Bit/Field	Name	Type	Reset	Description
16	DCINSS0	RO	0	<p>Digital Comparator Interrupt Status on SS0</p> <p>This bit is set when both the <code>INRDC</code> bit in the <b>ADCRIS</b> register and the <code>DCONSS0</code> bit in the <b>ADCIM</b> register are set, providing a level-base interrupt to the interrupt controller.</p> <p>This bit is cleared by writing a 1 to the appropriate location in the <b>ADDCISC</b> register. Clearing the <b>ADDCISC</b> register clears the <code>INRDC</code> bit.</p>
15:4	Reserved	RO	0x000	<p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>
3	IN3	R/W1C	0	<p>SS3 Interrupt Status and Clear</p> <p>This bit is set when both the <code>INR3</code> bit in the <b>ADCRIS</b> register and the <code>MASK3</code> bit in the <b>ADCIM</b> register are set, providing a level-based interrupt to the interrupt controller.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the <code>INR3</code> bit.</p>
2	IN2	R/W1C	0	<p>SS2 Interrupt Status and Clear</p> <p>This bit is set when both the <code>INR2</code> bit in the <b>ADCRIS</b> register and the <code>MASK2</code> bit in the <b>ADCIM</b> register are set, providing a level-based interrupt to the interrupt controller.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the <code>INR2</code> bit.</p>
1	IN1	R/W1C	0	<p>SS1 Interrupt Status and Clear</p> <p>This bit is set when both the <code>INR1</code> bit in the <b>ADCRIS</b> register and the <code>MASK1</code> bit in the <b>ADCIM</b> register are set, providing a level-based interrupt to the interrupt controller.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the <code>INR1</code> bit.</p>
0	IN0	R/W1C	0	<p>SS0 Interrupt Status and Clear</p> <p>This bit is set when both the <code>INR0</code> bit in the <b>ADCRIS</b> register and the <code>MASK0</code> bit in the <b>ADCIM</b> register are set, providing a level-based interrupt to the interrupt controller.</p> <p>This bit is cleared by writing a 1. Clearing this bit also clears the <code>INR0</code> bit.</p>

### Register 5: ADC Overflow Status (ADCOSTAT), offset 0x010

This register indicates overflow conditions in the sample sequencer FIFOs. Once the overflow condition has been handled by software, the condition can be cleared by writing a 1 to the corresponding bit position.

#### ADC Overflow Status (ADCOSTAT)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x010  
 Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	Reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	UV3	R/W1C	0	<p>SS3 FIFO Underflow</p> <p>This bit is set when the FIFO for Sample Sequencer 3 has hit an underflow condition, meaning that the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned.</p> <p>This bit is cleared by writing a 1.</p>
2	UV2	R/W1C	0	<p>SS2 FIFO Underflow</p> <p>This bit is set when the FIFO for Sample Sequencer 2 has hit an underflow condition, meaning that the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned.</p> <p>This bit is cleared by writing a 1.</p>
1	UV1	R/W1C	0	<p>SS1 FIFO Underflow</p> <p>This bit is set when the FIFO for Sample Sequencer 1 has hit an underflow condition, meaning that the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned.</p> <p>This bit is cleared by writing a 1.</p>
0	UV0	R/W1C	0	<p>SS0 FIFO Underflow</p> <p>This bit is set when the FIFO for Sample Sequencer 0 has hit an underflow condition, meaning that the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned.</p> <p>This bit is cleared by writing a 1.</p>

### Register 8: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020

This register sets the priority for each of the sample sequencers. Out of reset, Sequencer 0 has the highest priority, and Sequencer 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority for the ADC to operate properly.

#### ADC Sample Sequencer Priority (ADCSSPRI)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x020  
 Type R/W, reset 0x0000.3210

Bit/Field	Name	Type	Reset	Description
31:14	Reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13:12	SS3	R/W	0x3	SS3 Priority  This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 3. A priority encoding of 0x0 is highest and 0x3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.
11:10	Reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:8	SS2	R/W	0x2	SS2 Priority  This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 2. A priority encoding of 0x0 is highest and 0x3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.
7:6	Reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:4	SS1	R/W	0x1	SS1 Priority  This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 1. A priority encoding of 0x0 is highest and 0x3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.
3:2	Reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
1:0	SS0	R/W	0x0	SS0 Priority  This field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 0. A priority encoding of 0x0 is highest and 0x3 is lowest. The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.

### Register 9: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate **SS** bits should be set along with the **SYNCWAIT** bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate **SS** bits set along with the **GSYNC** bit. All of the ADC modules then begin concurrent sampling according to their configuration.

#### ADC Processor Sample Sequence Initiate (ADCPSSI)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x028  
 Type WO, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GSYNC	Reserved			SYNCWAIT	Reserved										
Type	R/W	WO	WO	WO	R/W	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO
Reset	0	-	-	-	0	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
31	GSYNC	R/W	0	Global Synchronize  When set, this bit initiates sampling in multiple ADC modules at the same time. Any ADC module that has been initialized by setting an <b>SS<sub>n</sub></b> bit and the <b>SYNCWAIT</b> bit starts sampling once this bit is written.  This bit is cleared once sampling has been initiated.
30:28	Reserved	WO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
27	SYNCWAIT	R/W	0	Synchronize Wait  When set, this bit allows the sample sequences to be initiated, but delays sampling until the <b>GSYNC</b> bit is set.  When this bit is clear, sampling begins when a sample sequence has been initiated.
26:4	Reserved	WO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

---

Bit/Field	Name	Type	Reset	Description
3	SS3	WO	-	<p>SS3 Initiate</p> <p>Setting this bit triggers sampling on Sample Sequencer 3, if the sequencer is enabled in the <b>ADCACTSS</b> register.</p> <p>Only a write by software is valid; a read of this register returns no meaningful data.</p>
2	SS2	WO	-	<p>SS2 Initiate</p> <p>Setting this bit triggers sampling on Sample Sequencer 2, if the sequencer is enabled in the <b>ADCACTSS</b> register.</p> <p>Only a write by software is valid; a read of this register returns no meaningful data.</p>
1	SS1	WO	-	<p>SS1 Initiate</p> <p>Setting this bit triggers sampling on Sample Sequencer 1, if the sequencer is enabled in the <b>ADCACTSS</b> register.</p> <p>Only a write by software is valid; a read of this register returns no meaningful data.</p>
0	SS0	WO	-	<p>SS0 Initiate</p> <p>Setting, this bit triggers sampling on Sample Sequencer 0, if the sequencer is enabled in the <b>ADCACTSS</b> register.</p> <p>Only a write by software is valid; a read of this register returns no meaningful data.</p>

### Register 10: ADC Sample Averaging Control (ADCSAC), offset 0x030

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from  $2^{AVG}$  consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG = 7 provides unpredictable results.

#### ADC Sample Averaging Control (ADCSAC)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x030  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	Reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	AVG	R/W	0x0	Hardware Averaging Control  Specifies the amount of hardware averaging that will be applied to ADC samples. The AVG field can be any value between 0 and 6. Entering a value of 7 creates unpredictable results.

Value	Description
0x0	No hardware oversampling
0x1	2x hardware oversampling
0x2	4x hardware oversampling
0x3	8x hardware oversampling
0x4	16x hardware oversampling
0x5	32x hardware oversampling
0x6	64x hardware oversampling
0x7	Reserved

## Register 11: ADC Digital Comparator Interrupt Status and Clear (ADCDCISC), offset 0x034

This register provides status and acknowledgement of digital comparator interrupts. One bit is provided for each comparator.

### ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)

ADC0 base: 0x4003.8000

### Register 13: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. This register is 32 bits wide and contains information for eight possible samples.

#### ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x040  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:28	MUX7	R/W	0x0	8th Sample Input Select  The MUX7 field is used during the eighth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. The value set here indicates the corresponding pin, for example, a value of 0x1 indicates the input is AIN1.
27:24	MUX6	R/W	0x0	7th Sample Input Select  The MUX6 field is used during the seventh sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
23:20	MUX5	R/W	0x0	6th Sample Input Select  The MUX5 field is used during the sixth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
19:16	MUX4	R/W	0x0	5th Sample Input Select  The MUX4 field is used during the fifth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
15:12	MUX3	R/W	0x0	4th Sample Input Select  The MUX3 field is used during the fourth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
11:8	MUX2	R/W	0x0	3rd Sample Input Select  The MUX2 field is used during the third sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.

---

Bit/Field	Name	Type	Reset	Description
7:4	MUX1	R/W	0x0	2nd Sample Input Select  The MUX1 field is used during the second sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
3:0	MUX0	R/W	0x0	1st Sample Input Select  The MUX0 field is used during the first sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.

**Register 14: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044**

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the `END` bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

## ADC Sample Sequence Control 0 (ADCSSCTL0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000

**Register 15: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048**

**Register 16: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068**

**Register 17: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088**

**Register 18: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8**

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x048  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:10	Reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:0	DATA	RO	0x000	Conversion Result Data

**Register 19: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C**

**Register 20: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C**

**Register 21: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C**

**Register 22: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC**

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x04C

**Register 25: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060**

**Register 26: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080**

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 490 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x060  
 Type R/W, reset 0x0000.0000

**Register 27: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064****Register 28: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the **END** bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 492 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

### Register 33: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register defines the analog input configuration for the sample executed with Sample Sequencer 3. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 490 for detailed bit descriptions.

#### ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x0A0  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	Reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	MUX0	R/W	0	1st Sample Input Select

### Register 34: ADC Sample Sequence Control 3 (ADCSSCTL3), offset 0x0A4

This register contains the configuration information for a sample executed with Sample Sequencer 3. The `END0` bit is always set as this sequencer can execute only one sample. This register is 4 bits wide and contains information for one possible sample. See the `ADCSSCTL0` register on page 492 for detailed bit descriptions.

#### ADC Sample Sequence Control 3 (ADCSSCTL3)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x0A4  
 Type R/W, reset 0x0000.0002

3:0	S0DCSEL	R/W	0x0	Sample 0 Digital Comparator Select

When the  $S_{0DCOP}$  bit in the **ADCSSOP3** register is set, this field indicates which digital comparator unit (and its associated set of control registers) receives the sample from Sample Sequencer 3.

**Note:** Values not listed are reserved.

Value	Description
0x0	Digital Comparator Unit 0 ( <b>ADCDCOMP0</b> and <b>ADCCCTL0</b> )
0x1	Digital Comparator Unit 1 ( <b>ADCDCOMP1</b> and <b>ADCCCTL1</b> )
0x2	Digital Comparator Unit 2 ( <b>ADCDCOMP2</b> and <b>ADCCCTL2</b> )
0x3	Digital Comparator Unit 3 ( <b>ADCDCOMP3</b> and <b>ADCCCTL3</b> )
0x4	Digital Comparator Unit 4 ( <b>ADCDCOMP4</b> and <b>ADCCCTL4</b> )
0x5	Digital Comparator Unit 5 ( <b>ADCDCOMP5</b> and <b>ADCCCTL5</b> )
0x6	Digital Comparator Unit 6 ( <b>ADCDCOMP6</b> and <b>ADCCCTL6</b> )
0x7	Digital Comparator Unit 7 ( <b>ADCDCOMP7</b> and <b>ADCCCTL7</b> )

### Register 37: ADC Digital Comparator Reset Initial Conditions (ADCDCRIC), offset 0xD00

This register provides the ability to reset any of the digital comparator interrupt or trigger functions back to their initial conditions. Resetting these functions ensures that the data that is being used by the interrupt and trigger functions in the digital comparator unit is not stale.

#### ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0xD00

25:16	COMP1	R/W	0x000	Compare 1  The value in this field is compared against the ADC conversion data. The result of the comparison is used to determine if the data lies within the high-band region.  Note that the value of COMP1 must be greater than or equal to the value of COMP0.
15:10	Reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:0	COMP0	R/W	0x000	Compare 0  The value in this field is compared against the ADC conversion data. The result of the comparison is used to determine if the data lies within the low-band region.

## 14 Universal Asynchronous Receivers/Transmitters (UARTs)

Each Stellaris® Universal Asynchronous Receiver/Transmitter (UART) has the following features:

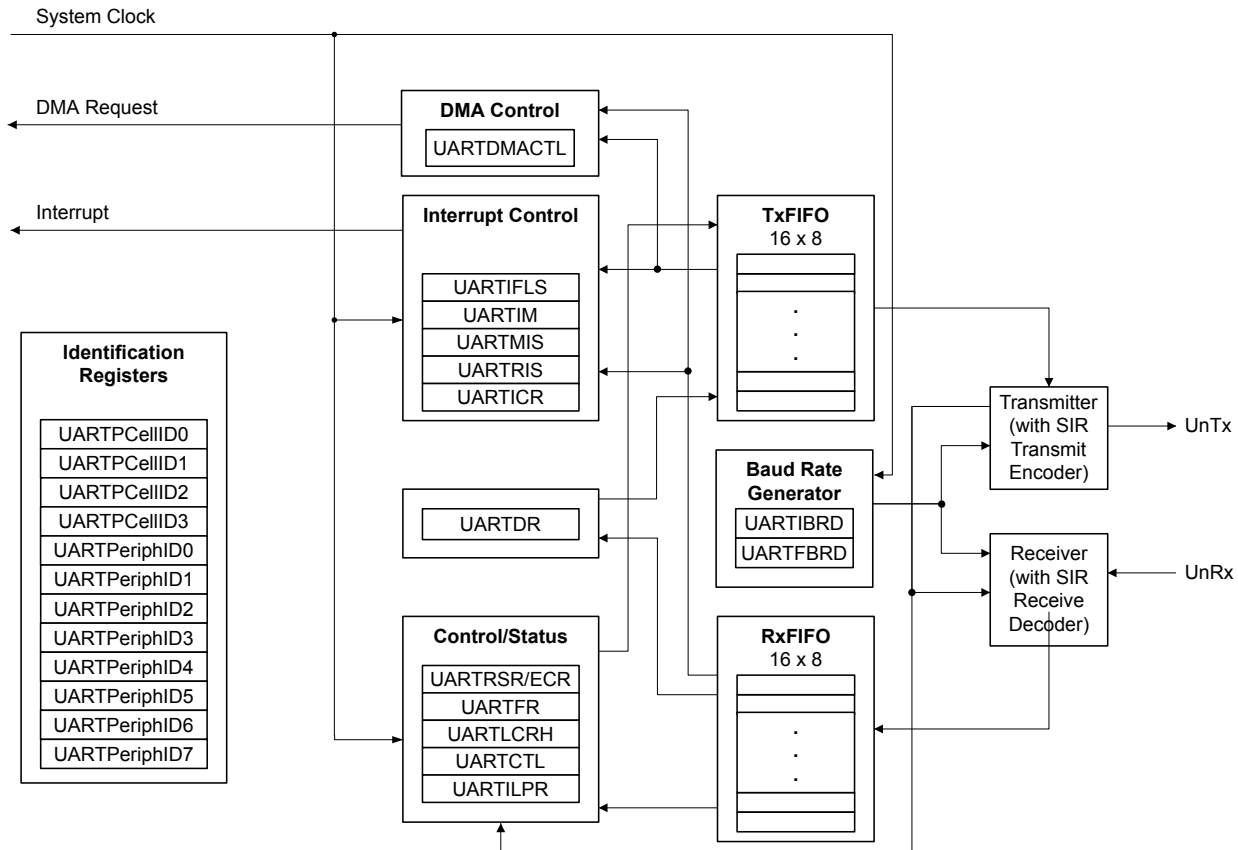

- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- LIN protocol support
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- False-start bit detection
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Full modem handshake support (on UART1)
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level

- Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level

## 14.1 Block Diagram

Figure 14-1. UART Module Block Diagram

## 14.2 Functional Description

Each Stellaris<sup>®</sup> UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 541). Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the UARTEEN bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART peripheral also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the **UARTCTL** register.

### 14.2.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit, and followed by the data

bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 14-2 on page 522 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

**Figure 14-2. UART Character Frame**

## 14.2.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divider allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 537) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 538). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where *UARTSysClk* is the system clock connected to the UART, and *ClkDiv* is either 16 (if *HSE* in **UARTCTL** is clear) or 8 (if *HSE* is set).

The 6-bit fractional number (that is to be loaded into the *DIVFRAC* bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as *Baud8* and *Baud16*, depending upon the setting of the *HSE* bit (bit 5) in **UARTCTL**). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during receive operations.

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 539), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write

- **UARTFBRD** write and **UARTLCRH** write

### 14.2.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The **BUSY** bit in the **UART Flag (UARTFR)** register (see page 534) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The **BUSY** bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the **UnRx** is continuously 1) and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of **Baud16** or fourth cycle of **Baud8** depending upon the setting of the **HSE** bit (bit 5) in **UARTCTL** (described in “Transmit/Receive Logic” on page 521).

The start bit is valid if **UnRx** is still low on the eighth cycle of **Baud16** (**HSE** clear) or the fourth cycle of **Baud 8** (**HSE** set), otherwise a false start bit is detected and it is ignored. Start bit errors can be viewed in the **UART Receive Status (UARTSR)** register (see page 532). If the start bit was valid, successive data bits are sampled on every 16th cycle of **Baud16** or 8th cycle of **Baud8** (that is, one bit period later) according to the programmed length of the data characters and value of the **HSE** bit in **UARTCTL**. The parity bit is then checked if parity mode was enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if **UnRx** is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO, with any error bits associated with that word.

### 14.2.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream, and half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output, and decoded input to the UART. The UART signal pins can be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW. This drives the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated **IrLPBaud16** signal (1.63  $\mu$ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCR** register. See page 536 for more information on IrDA low-power pulse-duration configuration.

Figure 14-3 on page 524 shows the UART transmit and receive signals, with and without IrDA modulation.

Figure 14-3. IrDA Data Modulation

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10 ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased, or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency, or receiver setup time.

### 14.2.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 (*SMART*) of the **UARTCTL** register is set, the **UnTX** line is used as a bit clock, and **UnRX** is used as the half-duplex communication line connected to the smartcard.

When using ISO 7816 mode, the **UARTLCRH** register must be set to transmit 8-bit words (*WLEN* bits 6:5 set to 0x3) with EVEN parity (*PEN* set to 1 and *EPS* set to 1). In this mode, the UART is automatically set to use 2 stop bits, and the *STP2* bit of the **UARTLCRH** register is ignored.

If a parity error is detected during transmission, the data line (**UARTRXD**) will be pulled Low during the second stop bit. This will trigger the UART to abort the transmission, flushing the transmit FIFO and discarding any data it contains, and raise a parity error interrupt, allowing software to detect the problem and initiate retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

### 14.2.6 LIN Support

The UART module offers hardware support for the LIN protocol as either a master or a slave. The LIN mode is enabled by setting the *LIN* bit in the **UARTCTL** register. A LIN message is identified by the use of a Sync Break at the beginning of the message. The Sync Break is a transmission of a series of 0s. The Sync Break is followed by the Sync data field (0x55).

The UART should be configured as followed to operate in LIN mode:

1. Configure the UART for 1 start bit, 8 data bits, no parity, and 1 stop bit. Enable the Transmit FIFO.

2. Set the LIN bit in the **UARTCTL** register.

When preparing to send a LIN message, the TXFIFO should contain the Sync data (0x55) at FIFO location 0, the Identifier data at location 1, the data to be transmitted, and the checksum in the final FIFO entry.

#### 14.2.6.1 LIN Master

The UART is enabled to be the LIN master by setting the **MASTER** bit in the **UARTLCTL** register. The length of the Sync Break is programmable using the **BLEN** field in the **UARTLCTL** register and can be 13-16 bits (baud clock cycles).

#### 14.2.6.2 LIN Slave

The LIN UART slave is required to adjust its baud rate to that of the LIN master. In slave mode, the LIN UART recognizes the Sync Break, which must be at least 13 bits in duration. A timer is provided to capture timing data on the 1st and 5th falling edges of the Sync field so that the baud rate can be adjusted to match the master.

After detecting a Sync Break, the UART waits for the synchronization field. The first falling edge generates an interrupt using the **LME1RIS** bit in the **UARTRIS** register, and the timer value is captured and stored in the **UARTLSS** register (T1). On the fifth falling edge, a second interrupt is generated using the **LME5RIS** bit in the **UARTRIS** register, and the timer value is captured again (T2). The actual baud rate can be calculated using  $(T2-T1)/8$ , and the local baud rate should be adjusted as needed.

#### 14.2.7 FIFO Operation

The UART has two 16-entry FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 530). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the **FEN** bit in **UARTLCRH** (page 539).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 534) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (**TXFE**, **TXFF**, **RXFE**, and **RXFF** bits) and the **UARTRSR** register shows overrun status via the **OE** bit.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 544). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include 1/8, 1/4, 1/2, 3/4, and 7/8. For example, if the 1/4 option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the 1/2 mark.

#### 14.2.8 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error

- Framing Error
- Receive Timeout
- Transmit (when condition defined in the `TXIFLSEL` bit in the **UARTIFLS** register is met, or, if the `EOT` bit in **UARTCTRL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the `RXIFLSEL` bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 550).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 546) by setting the corresponding `IM` bit to 1. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 548).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by setting the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 552).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

### 14.2.9 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work. This is accomplished by setting the `LBE` bit in the **UARTCTL** register (see page 541). In loopback mode, data transmitted on UnTx is received on the UnRx input.

### 14.2.10 DMA Operation

The UART provides an interface connected to the  $\mu$ DMA controller. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART will assert a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever there is any data in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending how the DMA channel is configured.

To enable DMA operation for the receive channel, the `RXDMAE` bit of the **DMA Control (UARTDMACTL)** register should be set. To enable DMA operation for the transmit channel, the `TXDMAE` bit of **UARTDMACTL** should be set. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the `DMAERR` bit of **UARTDMACR** is set, then when a receive error occurs, the DMA receive requests will be automatically disabled. This error condition can be cleared by clearing the UART error interrupt.

If DMA is enabled, then the  $\mu$ DMA controller will trigger an interrupt when a transfer is complete. The interrupt will occur on the UART interrupt vector. Therefore, if interrupts are used for UART

operation and DMA is enabled, the UART interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 226 for more details about programming the  $\mu$ DMA controller.

### 14.2.11 IrDA SIR block

The IrDA SIR block contains an IrDA serial IR (SIR) protocol encoder/decoder. When enabled, the SIR block uses the `UnTx` and `UnRx` pins for the SIR protocol, which should be connected to an IR transceiver.

The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception.

## 14.3 Initialization and Configuration

To use the UARTs, the peripheral clock must be enabled by setting the `UART0`, `UART1`, or `UART2` bits in the **RCGC1** register. See page 167. In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), since the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 522, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the `DIVINT` field of the **UARTIBRD** register (see page 537) should be set to 10. The value to be loaded into the **UARTFBRD** register (see page 538) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the `UARTEN` bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.

4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Optionally, configure the uDMA channel (see “Micro Direct Memory Access (μDMA)” on page 226) and enable the DMA option(s) in the **UARTDMACTL** register.
6. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

## 14.4 Register Map

Table 14-1 on page 528 lists the UART registers. The offset listed is a hexadecimal increment to the register’s address, relative to that UART’s base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000
- UART2: 0x4000.E000

Note that the UART module clock must be enabled before the registers can be programmed (see page 167).

**Note:** The UART must be disabled (see the **UARTEN** bit in the **UARTCTL** register on page 541) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

**Table 14-1. UART Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	UARTDR	R/W	0x0000.0000	UART Data	530

## 14.5 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

### Register 1: UART Data (UARTDR), offset 0x000

This register is the data register (the interface to the FIFOs).

When FIFOs are enabled, data written to this location is pushed onto the transmit FIFO. If FIFOs are disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If FIFOs are disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

#### UART Data (UARTDR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	OE	RO	0	UART Overrun Error  The OE values are defined as follows:  Value Description 0 There has been no data loss due to a FIFO overrun. 1 New data was received when the FIFO was full, resulting in data loss.
10	BE	RO	0	UART Break Error  This bit is set to 1 when a break condition is detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).  In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state) and the next valid start bit is received.

---

Bit/Field	Name	Type	Reset	Description
9	PE	RO	0	UART Parity Error This bit is set to 1 when the parity of the received data character does not match the parity defined by bits 2 and 7 of the <b>UARTLCRH</b> register. In FIFO mode, this error is associated with the character at the top of the FIFO.
8	FE	RO	0	UART Framing Error This bit is set to 1 when the received character does not have a valid stop bit (a valid stop bit is 1).
7:0	DATA	R/W	0	Data Transmitted or Received When written, the data that is to be transmitted via the UART. When read, the data that was received by the UART.

## Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared to 0 on reset.

### Reads

#### UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 Offset 0x004  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	OE	RO	0	<p>UART Overrun Error</p> <p>When this bit is set to 1, data is received and the FIFO is already full. This bit is cleared to 0 by a write to <b>UARTECR</b>.</p> <p>The FIFO contents remain valid since no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must now read the data in order to empty the FIFO.</p>
2	BE	RO	0	<p>UART Break Error</p> <p>This bit is set to 1 when a break condition is detected, indicating that the received data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).</p> <p>This bit is cleared to 0 by a write to <b>UARTECR</b>.</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.</p>

Bit/Field	Name	Type	Reset	Description
1	PE	RO	0	<p>UART Parity Error</p> <p>This bit is set to 1 when the parity of the received data character does not match the parity defined by bits 2 and 7 of the <b>UARTLCRH</b> register.</p> <p>This bit is cleared to 0 by a write to <b>UARTECR</b>.</p>
0	FE	RO	0	<p>UART Framing Error</p> <p>This bit is set to 1 when the received character does not have a valid stop bit (a valid stop bit is 1).</p> <p>This bit is cleared to 0 by a write to <b>UARTECR</b>.</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO.</p>

 UART2 base: 0x4000.E000  
 Offset 0x004  
 Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	WO	0	<p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>
7:0	DATA	WO	0	<p>Error Clear</p> <p>A write to this register of any data clears the framing, parity, break, and overrun flags.</p>

### Register 3: UART Flag (UARTFR), offset 0x018

The **UARTFR** register is the flag register. After reset, the **TXFF**, **RXFF**, and **BUSY** bits are 0, and **TXFE** and **RXFE** bits are 1. The **RI**, **DCD**, **DSR** and **CTS** bits indicate the modem status.

#### UART Flag (UARTFR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 Offset 0x018  
 Type RO, reset 0x0000.0090

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	RI	RO	0	Ring Indicator  This bit is 1 if the <b>U1RI</b> signal is asserted, or 0 otherwise.
7	TXFE	RO	1	UART Transmit FIFO Empty  The meaning of this bit depends on the state of the <b>FEN</b> bit in the <b>UARTLCRH</b> register.  If the FIFO is disabled ( <b>FEN</b> is 0), this bit is set when the transmit holding register is empty.  If the FIFO is enabled ( <b>FEN</b> is 1), this bit is set when the transmit FIFO is empty.
6	RXFF	RO	0	UART Receive FIFO Full  The meaning of this bit depends on the state of the <b>FEN</b> bit in the <b>UARTLCRH</b> register.  If the FIFO is disabled, this bit is set when the receive holding register is full.  If the FIFO is enabled, this bit is set when the receive FIFO is full.
5	TXFF	RO	0	UART Transmit FIFO Full  The meaning of this bit depends on the state of the <b>FEN</b> bit in the <b>UARTLCRH</b> register.  If the FIFO is disabled, this bit is set when the transmit holding register is full.  If the FIFO is enabled, this bit is set when the transmit FIFO is full.

Bit/Field	Name	Type	Reset	Description
4	RXFE	RO	1	<p>UART Receive FIFO Empty</p> <p>The meaning of this bit depends on the state of the <code>FEN</code> bit in the <code>UARTLCRH</code> register.</p> <p>If the FIFO is disabled, this bit is set when the receive holding register is empty.</p> <p>If the FIFO is enabled, this bit is set when the receive FIFO is empty.</p>
3	BUSY	RO	0	<p>UART Busy</p> <p>When this bit is 1, the UART is busy transmitting data. This bit remains set until the complete byte, including all stop bits, has been sent from the shift register.</p> <p>This bit is set as soon as the transmit FIFO becomes non-empty (regardless of whether UART is enabled).</p>
2	DCD	RO	0	<p>Data Carrier Detect</p> <p>This bit is 1 if the <code>U1DCD</code> signal is asserted, or 0 otherwise.</p>
1	DSR	RO	0	<p>Data Set Ready</p> <p>This bit is 1 if the <code>U1DSR</code> signal is asserted, or 0 otherwise.</p>
0	CTS	RO	0	<p>Clear To Send</p> <p>This bit is 1 if the <code>U1CTS</code> signal is asserted, or 0 otherwise.</p>

### Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register is an 8-bit read/write register that stores the low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared to 0 when reset.

The internal  $F_{IrLPBaud16}$  clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the  $F_{IrLPBaud16}$  clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = SysClk / F_{IrLPBaud16}$$

where  $F_{IrLPBaud16}$  is nominally 1.8432 MHz.

You must choose the divisor so that  $1.42 \text{ MHz} < F_{IrLPBaud16} < 2.12 \text{ MHz}$ , which results in a low-power pulse duration of 1.41–2.11  $\mu\text{s}$  (three times the period of  $F_{IrLPBaud16}$ ). The minimum frequency of  $F_{IrLPBaud16}$  ensures that pulses less than one period of  $F_{IrLPBaud16}$  are rejected, but that pulses greater than 1.4  $\mu\text{s}$  are accepted as valid pulses.

**Note:** Zero is an illegal value. Programming a zero value results in no  $F_{IrLPBaud16}$  pulses being generated.

#### UART IrDA Low-Power Register (UARTILPR)

UART0 base: 0x4000.C000

## Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 522 for configuration details.

### Register 6: UART Fractional Baud-Rate Divisor (UARTFBRD), offset 0x028

The **UARTFBRD** register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the **UARTFBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 522 for configuration details.

#### UART Fractional Baud-Rate Divisor (UARTFBRD)

## Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

4	FEN	R/W	0	<p>UART Enable FIFOs</p> <p>If this bit is set to 1, transmit and receive FIFO buffers are enabled (FIFO mode).</p> <p>When cleared to 0, FIFOs are disabled (Character mode). The FIFOs become 1-byte-deep holding registers.</p>										

Bit/Field	Name	Type	Reset	Description
3	STP2	R/W	0	<p>UART Two Stop Bits Select</p> <p>If this bit is set to 1, two stop bits are transmitted at the end of a frame. The receive logic does not check for two stop bits being received. The setting of this bit is ignored if the <code>SMART</code> bit is set in the <code>UARTCTL</code> register. When in 7816 smartcard mode, the number of stop bits is forced to 2.</p>
2	EPS	R/W	0	<p>UART Even Parity Select</p> <p>If this bit is set to 1, even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits.</p> <p>When cleared to 0, then odd parity is performed, which checks for an odd number of 1s.</p> <p>This bit has no effect when parity is disabled by the <code>PEN</code> bit.</p>
1	PEN	R/W	0	<p>UART Parity Enable</p> <p>If this bit is set to 1, parity checking and generation is enabled; otherwise, parity is disabled and no parity bit is added to the data frame.</p>
0	BRK	R/W	0	<p>UART Send Break</p> <p>If this bit is set to 1, a Low level is continually output on the <code>UnTX</code> output, after completing transmission of the current character. For the proper execution of the break command, the software must set this bit for at least two frames (character periods). For normal use, this bit must be cleared to 0.</p>

## Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set to 1.

To enable the UART module, the **UARTEN** bit must be set to 1. If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

**Note:** The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by disabling bit 4 (**FEN**) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

### UART Control (UARTCTL)

UART0 base: 0x4000.C000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15	CTSEN	R/W	0	Enable Clear To Send  If this bit is set to 1, CTS hardware flow control is enabled. Data is only transmitted when the <b>U1CTS</b> signal is asserted.
14	RTSEN	R/W	0	Enable Request to Send  If this bit is set to 1, RTS hardware flow control is enabled. Data is only requested (by asserting <b>U1RTS</b> ) when there is space in the receive FIFO for it to be stored.

Bit/Field	Name	Type	Reset	Description
13:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	RTS	R/W	0	Request to Send  This bit sets the state of the <code>U1RTS</code> output. If <code>RTSEN</code> is set to 1, the UART controls the state of <code>U1RTS</code> automatically and this bit is ignored. When flow control is selected, this bit becomes read-only. Read it to determine the state of the RTS handshake that is being controlled by the hardware.
10	DTR	R/W	0	Data Terminal Ready  This bit sets the state of the <code>U1DTR</code> output.
9	RXE	R/W	1	UART Receive Enable  If this bit is set to 1, the receive section of the UART is enabled. When the UART is disabled in the middle of a receive, it completes the current character before stopping.  <b>Note:</b> To enable reception, the <code>UARTEN</code> bit must also be set.
8	TXE	R/W	1	UART Transmit Enable  If this bit is set to 1, the transmit section of the UART is enabled. When the UART is disabled in the middle of a transmission, it completes the current character before stopping.  <b>Note:</b> To enable transmission, the <code>UARTEN</code> bit must also be set.
7	LBE	R/W	0	UART Loop Back Enable  If this bit is set to 1, the <code>UnTX</code> path is fed through the <code>UnRX</code> path.
6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	LIN	R/W	0	LIN Mode Enable  If set, the UART operates in LIN mode.
5	HSE	R/W	0	High-Speed Enable  If set, the UART is clocked using the system clock divided by 8. If clear, the system clock divided by 16 is used.  <b>Note:</b> System clock used is also dependent on the baud-rate divisor configuration (see page 537) and page 538).
4	EOT	R/W	0	End of Transmission  This bit determines the behavior of the <code>TXRIS</code> bit in the <code>UARTRIS</code> register. If the <code>EOT</code> bit is clear, the <code>TXRIS</code> bit is set when the transmit FIFO condition specified in <code>UARTIFLS</code> is met. If the <code>EOT</code> bit is set, the <code>TXRIS</code> bit is set only once all transmitted data, including stop bits, have cleared the serializer.

Bit/Field	Name	Type	Reset	Description
3	SMART	R/W	0	<p>ISO 7816 Smart Card Support</p> <p>The application must ensure that it sets 8-bit word length (<code>WLEN</code> set to 0x3) and even parity (<code>PEN</code> set to 1, <code>EPS</code> set to 1, <code>SPS</code> set to 0) in <b>UARTLCRH</b> when using ISO 7816 mode.</p> <p>In this mode, the value of the <code>STP2</code> bit in <b>UARTLCRH</b> is ignored and the number of stop bits is forced to 2. Note that the UART does not support automatic retransmission on parity errors. If a parity error is detected on transmission, all further transmit operations are aborted and software must handle retransmission of the affected byte or message.</p>
2	SIRLP	R/W	0	<p>UART SIR Low Power Mode</p> <p>This bit selects the IrDA encoding mode. If this bit is cleared to 0, low-level bits are transmitted as an active High pulse with a width of 3/16th of the bit period. If this bit is set to 1, low-level bits are transmitted with a pulse width which is 3 times the period of the <code>IrLPBaud16</code> input signal, regardless of the selected bit rate. Setting this bit uses less power, but might reduce transmission distances. See page 536 for more information.</p>
1	SIREN	R/W	0	<p>UART SIR Enable</p> <p>If this bit is set to 1, the IrDA SIR block is enabled, and the UART will transmit and receive data using SIR protocol.</p>
0	UARTEN	R/W	0	<p>UART Enable</p> <p>If this bit is set to 1, the UART is enabled. When the UART is disabled in the middle of transmission or reception, it completes the current character before stopping.</p>

### Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the **TXRIS** and **RXRIS** bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the **TXIFLSEL** and **RXIFLSEL** bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

#### UART Interrupt FIFO Level Select (UARTIFLS)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 Offset 0x034  
 Type R/W, reset 0x0000.0012

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:3	RXIFLSEL	R/W	0x2	UART Receive Interrupt FIFO Level Select

The trigger points for the receive interrupt are as follows:

Value	Description
0x0	RX FIFO $\geq$ 1/8 full
0x1	RX FIFO $\geq$ 1/4 full
0x2	RX FIFO $\geq$ 1/2 full (default)
0x3	RX FIFO $\geq$ 3/4 full
0x4	RX FIFO $\geq$ 7/8 full
0x5-0x7	Reserved

Bit/Field	Name	Type	Reset	Description
2:0	TXIFLSEL	R/W	0x2	UART Transmit Interrupt FIFO Level Select The trigger points for the transmit interrupt are as follows:  Value Description 0x0 TX FIFO $\leq$ 1/8 full 0x1 TX FIFO $\leq$ 1/4 full 0x2 TX FIFO $\leq$ 1/2 full (default) 0x3 TX FIFO $\leq$ 3/4 full 0x4 TX FIFO $\leq$ 7/8 full 0x5-0x7 Reserved  <b>Note:</b> If the EOT bit in <b>UARTCTL</b> is set (see page 541), the transmit interrupt is generated once the FIFO is completely empty and all data including stop bits have left the transmit serializer. In this case, the setting of TXIFLSEL is ignored.

## Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Writing a 1 to a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Writing a 0 prevents the raw interrupt signal from being sent to the interrupt controller.

### UART Interrupt Mask (UARTIM)

UART0 base: 0x4000.C000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:4	BLEN	R/W	0	Sync Break Length  Value Description 0x3 Sync break length is 16T bits 0x2 Sync break length is 15T bits 0x1 Sync break length is 14T bits 0x0 Sync break length is 13T bits (default)
3:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	MASTER	R/W	0	LIN Master Enable  When this bit is set, the UART begins operation as a LIN master.  When this bit is clear, the UART operates as a LIN slave.

### Register 16: UART LIN Snap Shot (UARTLSS), offset 0x094

The **UARTLSS** register captures the free-running timer value when either the Sync Edge 1 or the Sync Edge 5 is detected in LIN mode.

#### UART LIN Snap Shot (UARTLSS)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 Offset 0x094  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TSS	RO	0	Timer Snap Shot  This field contains the value of the free-running timer when either the Sync Edge 5 or the Sync Edge 1 was detected.

## Register 17: UART LIN Timer (UARTLTIM), offset 0x098

The **UARTLTIM** register contains the current timer value for the free-running timer that is used to calculate the baud rate when in LIN slave mode. The value in this register is used along with the value in the **UART LIN Snap Shot (UARTLSS)** register to adjust the baud rate to match that of the master.

### UART LIN Timer (UARTLTIM)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

Offset 0x098

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TIMER	RO	0	Timer Value This field contains the value of the free-running timer.

### Register 18: UART Peripheral Identification 4 (UARTPeriphID4), offset 0xFD0

The **UARTPeriphIDn** registers are hard-coded and the fields within the registers determine the reset values.

#### UART Peripheral Identification 4 (UARTPeriphID4)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 Offset 0xFD0  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID4	RO	0x00	UART Peripheral ID Register[7:0]  Can be used by software to identify the presence of this peripheral.

**Register 19: UART Peripheral Identification 5 (UARTPeriphID5), offset 0xFD4**

The **UARTPeriphIDn** registers are hard-coded and the fields within the registers determine the reset values.

## UART Peripheral Identification 5 (UARTPeriphID5)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

Offset 0xFD4

Type RO, reset 0x0000.0000

## 15 Synchronous Serial Interface (SSI)

The Stellaris<sup>®</sup> microcontroller includes two Synchronous Serial Interface (SSI) modules. Each SSI is a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces.

Each Stellaris<sup>®</sup> SSI module has the following features:

- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, 16 bits wide, 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when FIFO contains 4 entries

## 15.1 Block Diagram

Figure 15-1. SSI Module Block Diagram

## 15.2 Functional Description

The SSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The SSI also supports the DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the DMA module. DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 597).

## 15.2.1 Bit Rate Generation

The SSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (FSysClk). The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 591). The clock is further divided by a value from 1 to 256, which is  $1 + SCR$ , where *SCR* is the value programmed in the **SSI Control0 (SSICR0)** register (see page 584).

The frequency of the output clock SSIClk is defined by:

$$SSIClk = F_{SysClk} / (CPSDVSR * (1 + SCR))$$

**Note:** Although the SSIClk transmit clock can theoretically be 40 MHz, the module may not be able to operate at that speed. For master mode, the system clock must be at least two times faster than the SSIClk. For slave mode, the system clock must be at least 12 times faster than the SSIClk.

See “Synchronous Serial Interface (SSI)” on page 1013 to view SSI timing parameters.

## 15.2.2 FIFO Operation

### 15.2.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 588), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion and transmission to the attached slave or master, respectively, through the SSITx pin.

### 15.2.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register.

When configured as a master or slave, serial data received through the SSIRx pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

## 15.2.3 Interrupts

The SSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service
- Receive FIFO service
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission

All of the interrupt events are ORed together before being sent to the interrupt controller, so the SSI can only generate a single interrupt request to the controller at any given time. You can mask each

of the four individual maskable interrupts by setting the appropriate bits in the **SSI Interrupt Mask (SSIIM)** register (see page 592). Setting the appropriate mask bit to 1 enables the interrupt.

Provision of the individual outputs, as well as a combined interrupt output, allows use of either a global interrupt service routine, or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 594 and page 595, respectively).

## 15.2.4 Frame Formats

Each data frame is between 4 and 16 bits long, depending on the size of data programmed, and is transmitted starting with the MSB. There are three basic frame types that can be selected:

- Texas Instruments synchronous serial
- Freescale SPI
- MICROWIRE

For all three formats, the serial clock ( $SSIClk$ ) is held inactive while the SSI is idle, and  $SSIClk$  transitions at the programmed frequency only during active transmission or reception of data. The idle state of  $SSIClk$  is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI and MICROWIRE frame formats, the serial frame ( $SSIFSS$ ) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the  $SSIFSS$  pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SSI and the off-chip slave device drive their output data on the rising edge of  $SSIClk$ , and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the MICROWIRE format uses a special master-slave messaging technique, which operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

### 15.2.4.1 Texas Instruments Synchronous Serial Frame Format

Figure 15-2 on page 574 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

**Figure 15-2. TI Synchronous Serial Frame Format (Single Transfer)**

In this mode,  $SSIClk$  and  $SSIFss$  are forced Low, and the transmit data line  $SSITx$  is tristated whenever the SSI is idle. Once the bottom entry of the transmit FIFO contains data,  $SSIFss$  is pulsed High for one  $SSIClk$  period. The value to be transmitted is also transferred from the transmit FIFO to the serial shifter of the transmit logic. On the next rising edge of  $SSIClk$ , the MSB of the 4 to 16-bit data frame is shifted out on the  $SSITx$  pin. Likewise, the MSB of the received data is shifted onto the  $SSIRx$  pin by the off-chip serial slave device.

Both the SSI and the off-chip serial slave device then clock each data bit into their serial shifter on the falling edge of each  $SSIClk$ . The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of  $SSIClk$  after the LSB has been latched.

Figure 15-3 on page 574 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

**Figure 15-3. TI Synchronous Serial Frame Format (Continuous Transfer)**

#### 15.2.4.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the  $SSIFss$  signal behaves as a slave select. The main feature of the Freescale SPI format is that the inactive state and phase of the  $SSIClk$  signal are programmable through the  $SPO$  and  $SPH$  bits within the **SSISCR0** control register.

##### **SPO Clock Polarity Bit**

When the  $SPO$  clock polarity control bit is Low, it produces a steady state Low value on the  $SSIClk$  pin. If the  $SPO$  bit is High, a steady state High value is placed on the  $SSIClk$  pin when data is not being transferred.

### SPH Phase Control Bit

The *SPH* phase control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the *SPH* phase control bit is Low, data is captured on the first clock edge transition. If the *SPH* bit is High, data is captured on the second clock edge transition.

#### 15.2.4.3 Freescale SPI Frame Format with SPO=0 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with *SPO*=0 and *SPH*=0 are shown in Figure 15-4 on page 575 and Figure 15-5 on page 575.

**Figure 15-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0**

**Note:** Q is undefined.

**Figure 15-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0**

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the *SSIFss* master signal being driven Low. This causes slave data to be enabled onto the *SSIRx* input line of the master. The master *SSITx* output pad is enabled.

One half  $SSIClk$  period later, valid master data is transferred to the  $SSITx$  pin. Now that both the master and slave data have been set, the  $SSIClk$  master clock pin goes High after one further half  $SSIClk$  period.

The data is now captured on the rising and propagated on the falling edges of the  $SSIClk$  signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the  $SSIFss$  line is returned to its idle High state one  $SSIClk$  period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the  $SSIFss$  signal must be pulsed High between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the  $SPH$  bit is logic zero. Therefore, the master device must raise the  $SSIFss$  pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the  $SSIFss$  pin is returned to its idle state one  $SSIClk$  period after the last bit has been captured.

#### 15.2.4.4 Freescale SPI Frame Format with SPO=0 and SPH=1

The transfer signal sequence for Freescale SPI format with  $SPO=0$  and  $SPH=1$  is shown in Figure 15-6 on page 576, which covers both single and continuous transfers.

**Figure 15-6. Freescale SPI Frame Format with SPO=0 and SPH=1**

**Note:** Q is undefined.

In this configuration, during idle periods:

- $SSIClk$  is forced Low
- $SSIFss$  is forced High
- The transmit data line  $SSITx$  is arbitrarily forced Low
- When the SSI is configured as a master, it enables the  $SSIClk$  pad
- When the SSI is configured as a slave, it disables the  $SSIClk$  pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the  $SSIFss$  master signal being driven Low. The master  $SSITx$  output is enabled. After a further one half  $SSIClk$  period, both master and slave valid data is enabled onto their respective transmission lines. At the same time, the  $SSIClk$  is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the  $SSIClk$  signal.

In the case of a single word transfer, after all bits have been transferred, the  $SSIFss$  line is returned to its idle High state one  $SSIClk$  period after the last bit has been captured.

For continuous back-to-back transfers, the  $SSIF_{SS}$  pin is held Low between successive data words and termination is the same as that of the single word transfer.

#### 15.2.4.5 Freescale SPI Frame Format with SPO=1 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=1 and SPH=0 are shown in Figure 15-7 on page 577 and Figure 15-8 on page 577.

**Figure 15-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0**

**Note:** Q is undefined.

**Figure 15-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0**

In this configuration, during idle periods:

- SSIClk is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the  $SSIF_{SS}$  master signal being driven Low, which causes slave data to be immediately transferred onto the  $SSIR_x$  line of the master. The master  $SSIT_x$  output pad is enabled.

One half period later, valid master data is transferred to the  $SSIT_x$  line. Now that both the master and slave data have been set, the  $SSIClk$  master clock pin becomes Low after one further half  $SSIClk$  period. This means that data is captured on the falling edges and propagated on the rising edges of the  $SSIClk$  signal.

In the case of a single word transmission, after all bits of the data word are transferred, the  $SSIF_{SS}$  line is returned to its idle High state one  $SSIClk$  period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the  $SSIF_{SS}$  signal must be pulsed High between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the  $SPH$  bit is logic zero. Therefore, the master device must raise the  $SSIF_{SS}$  pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the  $SSIF_{SS}$  pin is returned to its idle state one  $SSIClk$  period after the last bit has been captured.

#### 15.2.4.6 Freescale SPI Frame Format with $SPO=1$ and $SPH=1$

The transfer signal sequence for Freescale SPI format with  $SPO=1$  and  $SPH=1$  is shown in Figure 15-9 on page 578, which covers both single and continuous transfers.

**Figure 15-9. Freescale SPI Frame Format with  $SPO=1$  and  $SPH=1$**

**Note:** Q is undefined.

In this configuration, during idle periods:

- $SSIClk$  is forced High
- $SSIF_{SS}$  is forced High
- The transmit data line  $SSITx$  is arbitrarily forced Low
- When the SSI is configured as a master, it enables the  $SSIClk$  pad
- When the SSI is configured as a slave, it disables the  $SSIClk$  pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the  $SSIF_{SS}$  master signal being driven Low. The master  $SSITx$  output pad is enabled. After a further one-half  $SSIClk$  period, both master and slave data are enabled onto their respective transmission lines. At the same time,  $SSIClk$  is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the  $SSIClk$  signal.

After all bits have been transferred, in the case of a single word transmission, the  $SSIF_{SS}$  line is returned to its idle high state one  $SSIClk$  period after the last bit has been captured.

For continuous back-to-back transmissions, the  $SSIF_{SS}$  pin remains in its active Low state, until the final bit of the last word has been captured, and then returns to its idle state as described above.

For continuous back-to-back transfers, the  $SSIF_{SS}$  pin is held Low between successive data words and termination is the same as that of the single word transfer.

#### 15.2.4.7 MICROWIRE Frame Format

Figure 15-10 on page 579 shows the MICROWIRE frame format, again for a single frame. Figure 15-11 on page 580 shows the same format when back-to-back frames are transmitted.

**Figure 15-10. MICROWIRE Frame Format (Single Frame)**

MICROWIRE format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex, using a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the SSI to the off-chip slave device. During this transmission, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of SSIFss causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic, and the MSB of the 8-bit control frame to be shifted out onto the SSITx pin. SSIFss remains Low for the duration of the frame transmission. The SSIRx pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on the rising edge of each SSIClk. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the SSI. Each bit is driven onto the SSIRx line on the falling edge of SSIClk. The SSI in turn latches each bit on the rising edge of SSIClk. At the end of the frame, for single transfers, the SSIFss signal is pulled High one clock period after the last bit has been latched in the receive serial shifter, which causes the data to be transferred to the receive FIFO.

**Note:** The off-chip slave device can tristate the receive line either on the falling edge of SSIClk after the LSB has been latched by the receive shifter, or when the SSIFss pin goes High.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the SSIFss line is continuously asserted (held Low) and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge of SSIClk, after the LSB of the frame has been latched into the SSI.

**Figure 15-11. MICROWIRE Frame Format (Continuous Transfer)**

In the MICROWIRE mode, the SSI slave samples the first bit of receive data on the rising edge of `SSIClk` after `SSIFss` has gone Low. Masters that drive a free-running `SSIClk` must ensure that the `SSIFss` signal has sufficient setup and hold margins with respect to the rising edge of `SSIClk`.

Figure 15-12 on page 580 illustrates these setup and hold time requirements. With respect to the `SSIClk` rising edge on which the first bit of receive data is to be sampled by the SSI slave, `SSIFss` must have a setup of at least two times the period of `SSIClk` on which the SSI operates. With respect to the `SSIClk` rising edge previous to this edge, `SSIFss` must have a hold of at least one `SSIClk` period.

**Figure 15-12. MICROWIRE Frame Format, SSIFss Input Setup and Hold Requirements**

### 15.2.5 DMA Operation

The SSI peripheral provides an interface connected to the  $\mu$ DMA controller. The DMA operation of the SSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When DMA operation is enabled, the SSI will assert a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever there is any data in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending how the DMA channel is configured. To enable DMA operation for the receive channel, the `RXDMAE` bit of the **DMA Control (SSIDMACTL)** register should be set. To enable DMA operation for the transmit channel, the `TXDMAE` bit of **SSIDMACTL** should be set. If DMA is enabled, then the  $\mu$ DMA controller will trigger an interrupt when a transfer is complete. The interrupt will occur on the SSI interrupt vector. Therefore, if interrupts are used for SSI operation and DMA is enabled, the SSI interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

See “Micro Direct Memory Access (μDMA)” on page 226 for more details about programming the μDMA controller.

## 15.3 Initialization and Configuration

To use the SSI, its peripheral clock must be enabled by setting the *SSI* bit in the **RCGC1** register. See page 167. In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.

For each of the frame formats, the SSI is configured using the following steps:

1. Ensure that the *SSE* bit in the **SSICR1** register is disabled before making any configuration changes.
2. Select whether the SSI is a master or slave:
  - a. For master operations, set the **SSICR1** register to 0x0000.0000.
  - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
  - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the clock prescale divisor by writing the **SSICPSR** register.
4. Write the **SSICR0** register with the following configuration:
  - Serial clock rate (*SCR*)
  - Desired clock phase/polarity, if using Freescale SPI mode (*SPH* and *SPO*)
  - The protocol mode: Freescale SPI, TI SSF, MICROWIRE (*FRF*)
  - The data size (*DSS*)
5. Optionally, configure the μDMA channel (see “Micro Direct Memory Access (μDMA)” on page 226) and enable the DMA option(s) in the **SSIDMACTL** register.
6. Enable the SSI by setting the *SSE* bit in the **SSICR1** register.

As an example, assume the SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (*SPO*=1, *SPH*=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$F_{SSIClk} = F_{SysClk} / (CPSDVSR * (1 + SCR))$$

$$1 \times 10^6 = 20 \times 10^6 / (CPSDVSR * (1 + SCR))$$

In this case, if *CPSDVSR*=2, *SCR* must be 9.

The configuration sequence would be as follows:

1. Ensure that the `SSE` bit in the **SSICR1** register is disabled.
2. Write the **SSICR1** register with a value of `0x0000.0000`.
3. Write the **SSICPSR** register with a value of `0x0000.0002`.
4. Write the **SSICR0** register with a value of `0x0000.09C7`.
5. The SSI is then enabled by setting the `SSE` bit in the **SSICR1** register to 1.

## 15.4 Register Map

Table 15-1 on page 582 lists the SSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that SSI module's base address:

- SSI0: `0x4000.8000`
- SSI1: `0x4000.9000`

Note that the SSI module clock must be enabled before the registers can be programmed (see page 167).

**Note:** The SSI must be disabled (see the `SSE` bit in the **SSICR1** register) before any of the control registers are reprogrammed.

**Table 15-1. SSI Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	SSICR0	R/W	0x0000.0000	SSI Control 0	584

## 15.5 Register Descriptions

The remainder of this section lists and describes the SSI registers, in numerical order by address offset.

**Register 1: SSI Control 0 (SSICR0), offset 0x000**

**SSICR0** is control register 0 and contains bit fields that control various functions within the SSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

## SSI Control 0 (SSICR0)

SSI0 base: 0x4000.8000  
 SSI1 base: 0x4000.9000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	SCR								SPH	SPO	FRF			DSS			
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:8	SCR	R/W	0x0000	SSI Serial Clock Rate  The value <i>SCR</i> is used to generate the transmit and receive bit rate of the SSI. The bit rate is:  $BR = FSSIClk / (CPSDVSr * (1 + SCR))$  where <i>CPSDVSr</i> is an even value from 2-254 programmed in the <b>SSICPSR</b> register, and <i>SCR</i> is a value from 0-255.
7	SPH	R/W	0	SSI Serial Clock Phase  This bit is only applicable to the Freescale SPI Format.  The <i>SPH</i> control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge.  When the <i>SPH</i> bit is 0, data is captured on the first clock edge transition. If <i>SPH</i> is 1, data is captured on the second clock edge transition.
6	SPO	R/W	0	SSI Serial Clock Polarity  This bit is only applicable to the Freescale SPI Format.  When the <i>SPO</i> bit is 0, it produces a steady state Low value on the <i>SSIClk</i> pin. If <i>SPO</i> is 1, a steady state High value is placed on the <i>SSIClk</i> pin when data is not being transferred.

Bit/Field	Name	Type	Reset	Description
5:4	FRF	R/W	0x0	SSI Frame Format Select The FRF values are defined as follows:  Value Frame Format 0x0 Freescale SPI Frame Format 0x1 Texas Instruments Synchronous Serial Frame Format 0x2 MICROWIRE Frame Format 0x3 Reserved
3:0	DSS	R/W	0x00	SSI Data Size Select The DSS values are defined as follows:  Value Data Size 0x0-0x2 Reserved 0x3 4-bit data 0x4 5-bit data 0x5 6-bit data 0x6 7-bit data 0x7 8-bit data 0x8 9-bit data 0x9 10-bit data 0xA 11-bit data 0xB 12-bit data 0xC 13-bit data 0xD 14-bit data 0xE 15-bit data 0xF 16-bit data

**Register 2: SSI Control 1 (SSICR1), offset 0x004**

**SSICR1** is control register 1 and contains bit fields that control various functions within the SSI module. Master and slave mode functionality is controlled by this register.

## SSI Control 1 (SSICR1)

SSI0 base: 0x4000.8000  
 SSI1 base: 0x4000.9000  
 Offset 0x004  
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved												EOT	SOD	MS	SSE	LBM

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	EOT	R/W	0	End of Transmission  When set to 1, this bit enables the End of Transmit interrupt mode for the TXIM interrupt.
3	SOD	R/W	0	SSI Slave Mode Output Disable  This bit is relevant only in the Slave mode ( $MS=1$ ). In multiple-slave systems, it is possible for the SSI master to broadcast a message to all slaves in the system while ensuring that only one slave drives data onto the serial output line. In such systems, the TXD lines from multiple slaves could be tied together. To operate in such a system, the SOD bit can be configured so that the SSI slave does not drive the $SSITx$ pin.  The SOD values are defined as follows:  Value Description 0 SSI can drive $SSITx$ output in Slave Output mode. 1 SSI must not drive the $SSITx$ output in Slave mode.
2	MS	R/W	0	SSI Master/Slave Select  This bit selects Master or Slave mode and can be modified only when SSI is disabled ( $SSE=0$ ).  The MS values are defined as follows:  Value Description 0 Device configured as a master. 1 Device configured as a slave.

Bit/Field	Name	Type	Reset	Description						
1	SSE	R/W	0	<p>SSI Synchronous Serial Port Enable</p> <p>Setting this bit enables SSI operation.</p> <p>The <code>SSE</code> values are defined as follows:</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>SSI operation disabled.</td> </tr> <tr> <td>1</td> <td>SSI operation enabled.</td> </tr> </tbody> </table> <p><b>Note:</b> This bit must be set to 0 before any control registers are reprogrammed.</p>	Value	Description	0	SSI operation disabled.	1	SSI operation enabled.
Value	Description									
0	SSI operation disabled.									
1	SSI operation enabled.									
0	LBM	R/W	0	<p>SSI Loopback Mode</p> <p>Setting this bit enables Loopback Test mode.</p> <p>The <code>LBM</code> values are defined as follows:</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Normal serial port operation enabled.</td> </tr> <tr> <td>1</td> <td>Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.</td> </tr> </tbody> </table>	Value	Description	0	Normal serial port operation enabled.	1	Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.
Value	Description									
0	Normal serial port operation enabled.									
1	Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.									

**Register 3: SSI Data (SSIDR), offset 0x008**

**SSIDR** is the data register and is 16-bits wide. When **SSIDR** is read, the entry in the receive FIFO (pointed to by the current FIFO read pointer) is accessed. As data values are removed by the SSI receive logic from the incoming data frame, they are placed into the entry in the receive FIFO (pointed to by the current FIFO write pointer).

When **SSIDR** is written to, the entry in the transmit FIFO (pointed to by the write pointer) is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. It is loaded into the transmit serial shifter, then serially shifted out onto the **SSITx** pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

When the SSI is programmed for MICROWIRE frame format, the default size for transmit data is eight bits (the most significant byte is ignored). The receive data size is controlled by the programmer. The transmit FIFO and the receive FIFO are not cleared even when the **SSE** bit in the **SSICR1** register is set to zero. This allows the software to fill the transmit FIFO before enabling the SSI.

**SSI Data (SSIDR)**

SSI0 base: 0x4000.8000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	DATA	R/W	0x0000	SSI Receive/Transmit Data  A read operation reads the receive FIFO. A write operation writes the transmit FIFO.  Software must right-justify data when the SSI is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by the transmit logic. The receive logic automatically right-justifies the data.

## Register 4: SSI Status (SSISR), offset 0x00C

SSISR is a status register that contains bits that indicate the FIFO fill status and the SSI busy status.

### SSI Status (SSISR)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x00C

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	BSY	RO	0	SSI Busy Bit  The BSY values are defined as follows:  Value Description 0 SSI is idle. 1 SSI is currently transmitting and/or receiving a frame, or the transmit FIFO is not empty.
3	RFF	RO	0	SSI Receive FIFO Full  The RFF values are defined as follows:  Value Description 0 Receive FIFO is not full. 1 Receive FIFO is full.
2	RNE	RO	0	SSI Receive FIFO Not Empty  The RNE values are defined as follows:  Value Description 0 Receive FIFO is empty. 1 Receive FIFO is not empty.

Bit/Field	Name	Type	Reset	Description
1	TNF	RO	1	SSI Transmit FIFO Not Full The <b>TNF</b> values are defined as follows:  Value Description 0 Transmit FIFO is full. 1 Transmit FIFO is not full.
0	TFE	RO	1	SSI Transmit FIFO Empty The <b>TFE</b> values are defined as follows:  Value Description 0 Transmit FIFO is not empty. 1 Transmit FIFO is empty.

## Register 5: SSI Clock Prescale (SSICPSR), offset 0x010

**SSICPSR** is the clock prescale register and specifies the division factor by which the system clock must be internally divided before further use.

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

### SSI Clock Prescale (SSICPSR)

SSI0 base: 0x4000.8000  
 SSI1 base: 0x4000.9000  
 Offset 0x010  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CPSDVSR	R/W	0x00	SSI Clock Prescale Divisor  This value must be an even number from 2 to 254, depending on the frequency of <code>SSIClk</code> . The LSB always returns 0 on reads.

**Register 6: SSI Interrupt Mask (SSIIM), offset 0x014**

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared to 0 on reset.

On a read, this register gives the current value of the mask on the relevant interrupt. A write of 1 to the particular bit sets the mask, enabling the interrupt to be read. A write of 0 clears the corresponding mask.

**SSI Interrupt Mask (SSIIM)**

SSI0 base: 0x4000.8000  
 SSI1 base: 0x4000.9000  
 Offset 0x014

1	RTIC	W1C	0	SSI Receive Time-Out Interrupt Clear  The <b>RTIC</b> values are defined as follows:  Value Description 0 No effect on interrupt. 1 Clears interrupt.
0	RORIC	W1C	0	SSI Receive Overrun Interrupt Clear  The <b>RORIC</b> values are defined as follows:  Value Description 0 No effect on interrupt. 1 Clears interrupt.

## Register 10: SSI DMA Control (SSIDMACTL), offset 0x024

The **SSIDMACTL** register is the DMA control register.

### SSI DMA Control (SSIDMACTL)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0x024

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved														TXDMAE	RXDMAE	
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	TXDMAE	R/W	0	Transmit DMA Enable If this bit is set to 1, DMA for the transmit FIFO is enabled.
0	RXDMAE	R/W	0	Receive DMA Enable If this bit is set to 1, DMA for the receive FIFO is enabled.

### Register 11: SSI Peripheral Identification 4 (SSIPeriphID4), offset 0xFD0

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

#### SSI Peripheral Identification 4 (SSIPeriphID4)

SSI0 base: 0x4000.8000  
 SSI1 base: 0x4000.9000  
 Offset 0xFD0  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID4	RO	0x00	SSI Peripheral ID Register[7:0]  Can be used by software to identify the presence of this peripheral.

## Register 12: SSI Peripheral Identification 5 (SSIPeriphID5), offset 0xFD4

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

### SSI Peripheral Identification 5 (SSIPeriphID5)

SSI0 base: 0x4000.8000

SSI1 base: 0x4000.9000

Offset 0xFD4

Type RO, reset 0x0000.0000

## 16 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacture. The LM3S9792 microcontroller includes two I<sup>2</sup>C modules, providing the ability to interact (both send and receive) with other I<sup>2</sup>C devices on the bus.

The Stellaris<sup>®</sup> I<sup>2</sup>C interface has the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both sending and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Two transmission speeds: Standard (100 Kbps) and Fast (400 Kbps)
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
  - Slave generates interrupts when data has been sent or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

## 16.1 Block Diagram

Figure 16-1. I<sup>2</sup>C Block Diagram

## 16.2 Functional Description

Each I<sup>2</sup>C module is comprised of both master and slave functions which are implemented as separate peripherals. For proper operation, the SDA and SCL pins must be connected to bi-directional open-drain pads. A typical I<sup>2</sup>C bus configuration is shown in Figure 16-2 on page 611.

See “Inter-Integrated Circuit (I<sup>2</sup>C) Interface” on page 1014 for I<sup>2</sup>C timing diagrams.

Figure 16-2. I<sup>2</sup>C Bus Configuration

### 16.2.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on Stellaris<sup>®</sup> microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I<sup>2</sup>C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 612) is unrestricted, but each byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

### 16.2.1.1 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 16-3 on page 612.

Figure 16-3. START and STOP Conditions

When operating in slave mode, two bits in the **I2CSRIS** register indicate detection of start and stop conditions on the bus; while two bits in the **I2CSMIS** register allow start and stop conditions to be promoted to controller interrupts (when interrupts are enabled).

### 16.2.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 16-4 on page 612. After the START condition, a slave address is sent. This address is 7-bits long followed by an eighth bit, which is a data direction bit (**R/S** bit in the **I2CMSA** register). A zero indicates a transmit operation (send), and a one indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/send formats are then possible within a single transfer.

Figure 16-4. Complete Data Transfer with a 7-Bit Address

The first seven bits of the first byte make up the slave address (see Figure 16-5 on page 612). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master will write (send) data to the selected slave, and a one in this position means that the master will receive data from the slave.

Figure 16-5. R/S Bit in First Byte

### 16.2.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 16-6 on page 613).

**Figure 16-6. Data Validity During Bit Transfer on the I<sup>2</sup>C Bus**

### 16.2.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data sent out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 613.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Since the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

### 16.2.1.5 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a '1' (High) on SDA while another master transmits a '0' (Low) will switch off its data output stage and retire until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

## 16.2.2 Available Speed Modes

The I<sup>2</sup>C clock rate is determined by the parameters: CLK\_PRD, TIMER\_PRD, SCL\_LP, and SCL\_HP. where:

CLK\_PRD is the system clock period

SCL\_LP is the low phase of SCL (fixed at 6)

SCL\_HP is the high phase of SCL (fixed at 4)

TIMER\_PRD is the programmed value in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register (see page 631).

The I<sup>2</sup>C clock period is calculated as follows:

$$SCL\_PERIOD = 2 * (1 + TIMER\_PRD) * (SCL\_LP + SCL\_HP) * CLK\_PRD$$

For example:

CLK\_PRD = 50 ns  
 TIMER\_PRD = 2  
 SCL\_LP=6  
 SCL\_HP=4

yields a SCL frequency of:

$$1/T = 333 \text{ Khz}$$

Table 16-1 on page 614 gives examples of timer period, system clock, and speed mode (Standard or Fast).

**Table 16-1. Examples of I<sup>2</sup>C Master Timer Period versus Speed Mode**

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode
4 MHz	0x01	100 Kbps	-	-
6 MHz	0x02	100 Kbps	-	-
12.5 MHz	0x06	89 Kbps	0x01	312 Kbps
16.7 MHz	0x08	93 Kbps	0x02	278 Kbps
20 MHz	0x09	100 Kbps	0x02	333 Kbps
25 MHz	0x0C	96.2 Kbps	0x03	312 Kbps
33 MHz	0x10	97.1 Kbps	0x04	330 Kbps
40 MHz	0x13	100 Kbps	0x04	400 Kbps
50 MHz	0x18	100 Kbps	0x06	357 Kbps

### 16.2.3 Interrupts

The I<sup>2</sup>C can generate interrupts when the following conditions are observed:

- Master transaction completed
- Master transaction error
- Slave transaction received
- Slave transaction requested
- Stop condition on bus detected
- Start condition on bus detected

There is a separate interrupt signal for the I<sup>2</sup>C master and I<sup>2</sup>C slave modules. While both modules can generate interrupts for multiple conditions, only a single interrupt signal is sent to the interrupt controller.

#### 16.2.3.1 I<sup>2</sup>C Master Interrupts

The I<sup>2</sup>C master module generates an interrupt when a transaction completes (either transmit or receive), or when an error occurs during a transaction. To enable the I<sup>2</sup>C master interrupt, software must write a '1' to the **I<sup>2</sup>C Master Interrupt Mask (I2CMIMR)** register. When an interrupt condition

is met, software must check the `ERROR` bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register to verify that an error didn't occur during the last transaction. An error condition is asserted if the last transaction wasn't acknowledge by the slave or if the master was forced to give up ownership of the bus due to a lost arbitration round with another master. If an error is not detected, the application can proceed with the transfer. The interrupt is cleared by writing a '1' to the **I<sup>2</sup>C Master Interrupt Clear (I2CMICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register.

### 16.2.3.2 I<sup>2</sup>C Slave Interrupts

The slave module can generate an interrupt when data has been received or requested. This interrupt is enabled by writing a 1 to the `DATAIM` bit in the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register. Software determines whether the module should write (transmit) or read (receive) data from the **I<sup>2</sup>C Slave Data (I2CSDR)** register, by checking the `RREQ` and `TREQ` bits of the **I<sup>2</sup>C Slave Control/Status (I2CSCR)** register. If the slave module is in receive mode and the first byte of a transfer is received, the `FBR` bit is set along with the `RREQ` bit. The interrupt is cleared by writing a 1 to the `DATAIC` bit in the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

In addition, the slave module can generate an interrupt when a start and stop condition is detected. These interrupts are enabled by writing a 1 to the `STARTIM` and `STOPIM` bits of the **I<sup>2</sup>C Slave Interrupt Mask (I2CSIMR)** register and cleared by writing a 1 to the `STOPIC` and `STARTIC` bits of the **I<sup>2</sup>C Slave Interrupt Clear (I2CSICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register.

### 16.2.4 Loopback Operation

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work. This is accomplished by setting the `LPBK` bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and slave modules are tied together.

### 16.2.5 Command Sequence Flow Charts

This section details the steps required to perform the various I<sup>2</sup>C transfer types in both master and slave mode.

#### 16.2.5.1 I<sup>2</sup>C Master Command Sequences

The figures that follow show the command sequences available for the I<sup>2</sup>C master.

Figure 16-7. Master Single SEND

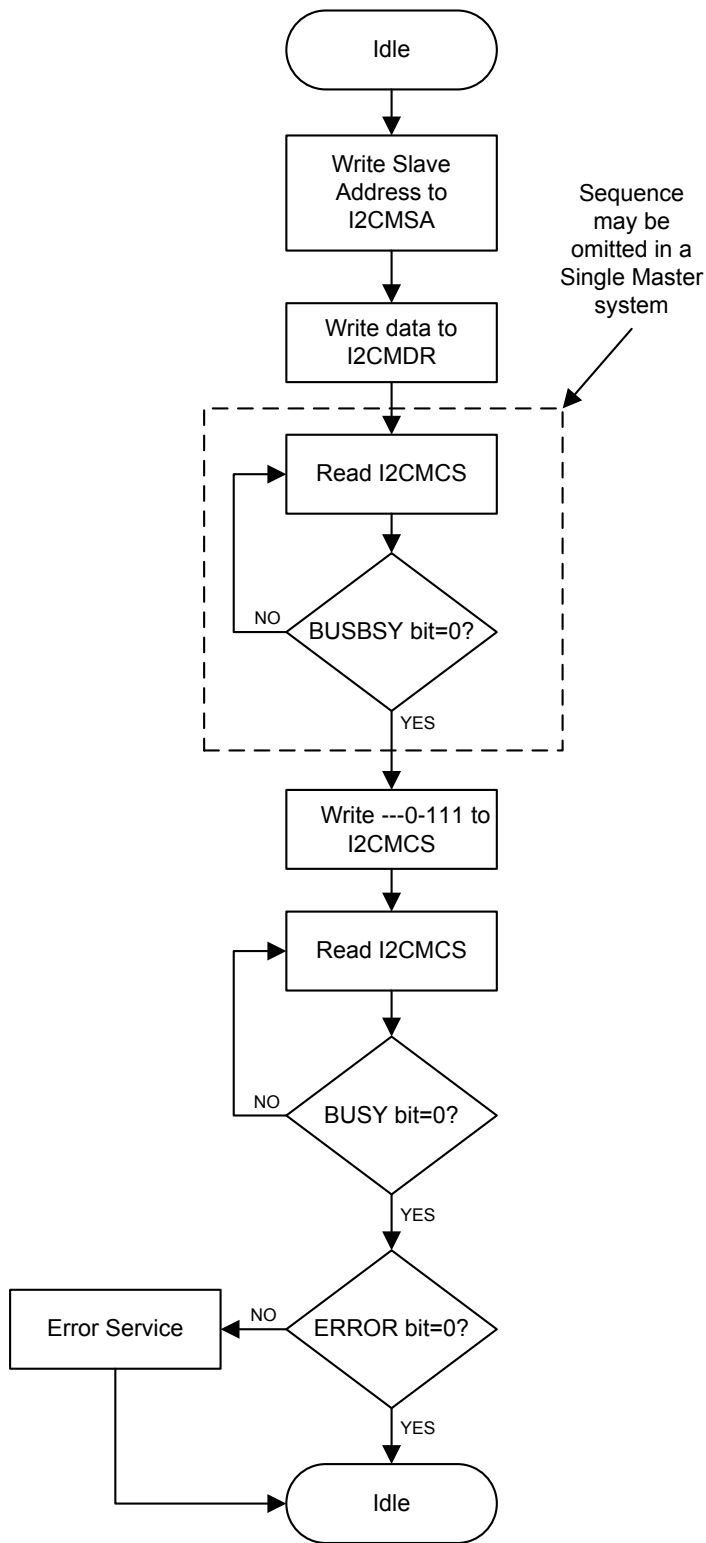

Figure 16-8. Master Single RECEIVE

Figure 16-9. Master Burst SEND

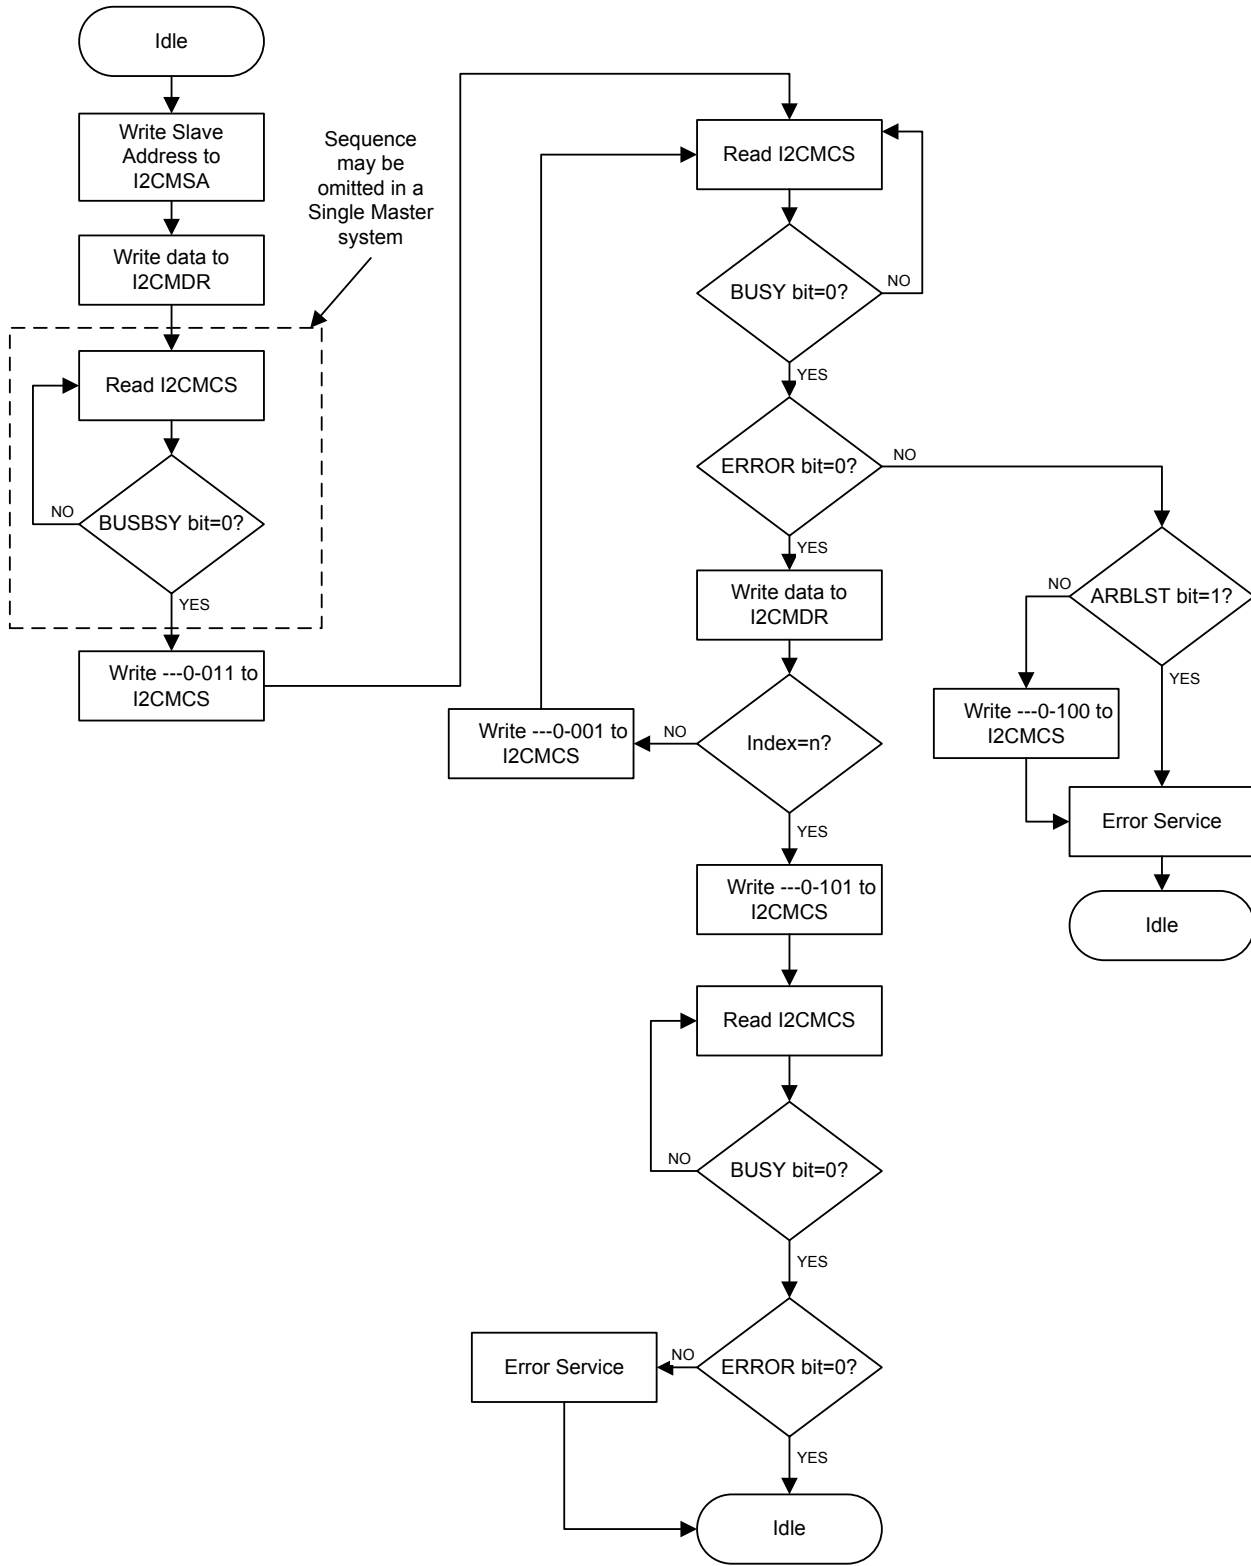

Figure 16-10. Master Burst RECEIVE

Figure 16-11. Master Burst RECEIVE after Burst SEND

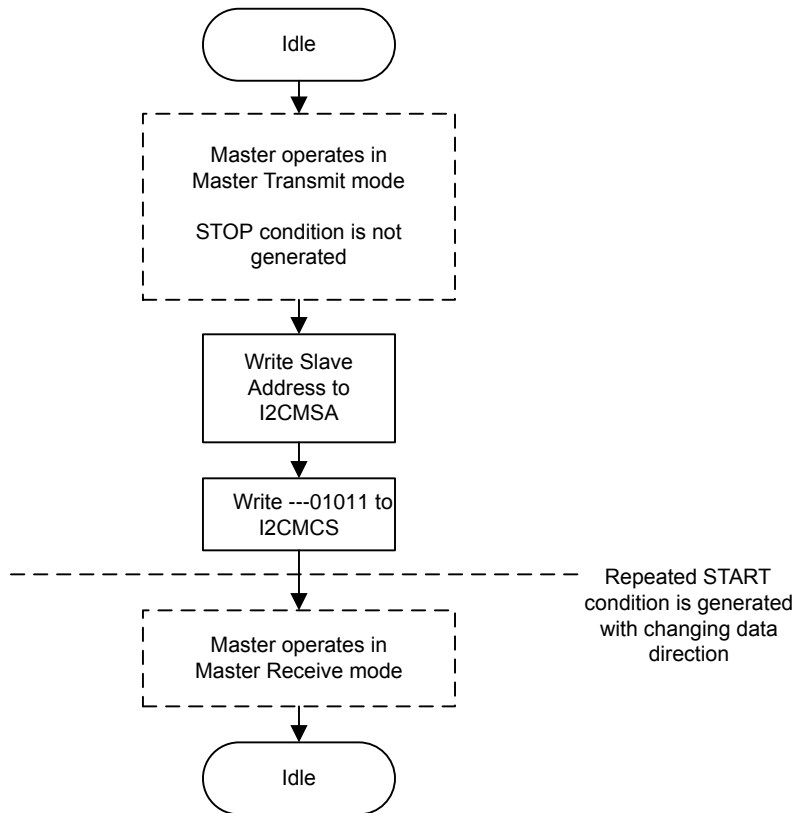

Figure 16-12. Master Burst SEND after Burst RECEIVE

### 16.2.5.2 I<sup>2</sup>C Slave Command Sequences

Figure 16-13 on page 622 presents the command sequence available for the I<sup>2</sup>C slave.

Figure 16-13. Slave Command Sequence

### 16.3 Initialization and Configuration

The following example shows how to configure the I<sup>2</sup>C module to send a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I<sup>2</sup>C clock by writing a value of 0x0000.1000 to the **RCGC1** register in the System Control module. See page 167.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. Also, be sure to enable the same pins for Open Drain operation.
4. Initialize the I<sup>2</sup>C Master by writing the **I2CMCR** register with a value of 0x0000.0020.
5. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```

TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;
TPR = (20MHz / (2 * (6 + 4) * 100000)) - 1;
TPR = 9

```

Write the **I2CMTPR** register with the value of 0x0000.0009.

6. Specify the slave address of the master and that the next operation will be a Send by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
7. Place data (byte) to be sent in the data register by writing the **I2CMDR** register with the desired data.
8. Initiate a single byte send of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
9. Wait until the transmission completes by polling the **I2CMCS** register's **BUSBSY** bit until it has been cleared.

## 16.4 Register Map

Table 16-2 on page 623 lists the I<sup>2</sup>C registers. All addresses given are relative to the I<sup>2</sup>C base addresses for the master and slave:

- I<sup>2</sup>C Master 0: 0x4002.0000
- I<sup>2</sup>C Slave 0: 0x4002.0800
- I<sup>2</sup>C Master 1: 0x4002.1000
- I<sup>2</sup>C Slave 1: 0x4002.1800

Note that the I<sup>2</sup>C module clock must be enabled before the registers can be programmed (see page 167).

## 16.5 Register Descriptions (I<sup>2</sup>C Master)

The remainder of this section lists and describes the I<sup>2</sup>C master registers, in numerical order by address offset. See also “Register Descriptions (I<sup>2</sup>C Slave)” on page 636.

## Register 1: I<sup>2</sup>C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Send (Low).

### I2C Master Slave Address (I2CMSA)

I2C Master 0 base: 0x4002.0000

I2C Master 1 base: 0x4002.1000

Offset 0x000

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved								SA							R/S
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:1	SA	R/W	0	I <sup>2</sup> C Slave Address  This field specifies bits A6 through A0 of the slave address.
0	R/S	R/W	0	Receive/Send  The R/S bit specifies if the next operation is a Receive (High) or Send (Low).  Value Description 0 Send. 1 Receive.

## Register 2: I<sup>2</sup>C Master Control/Status (I2CMCS), offset 0x004

This register accesses four control bits when written, and accesses seven status bits when read.

The status register consists of seven bits, which when read determine the state of the I<sup>2</sup>C bus controller.

The control register consists of four bits: the RUN, START, STOP, and ACK bits. The START bit causes the generation of the START, or REPEATED START condition.

The STOP bit determines if the cycle stops at the end of the data cycle, or continues on to a burst. To generate a single send cycle, the I<sup>2</sup>C Master Slave Address (I2CMSA) register is written with the desired address, the R/S bit is set to 0, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), the interrupt pin becomes active and the data may be read from the I2CMDR register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit must be set normally to logic 1. This causes the I<sup>2</sup>C bus controller to send an acknowledge automatically after each byte. This bit must be reset when the I<sup>2</sup>C bus controller requires no further data to be sent from the slave transmitter.

### Reads

#### I2C Master Control/Status (I2CMCS)

I2C Master 0 base: 0x4002.0000

I2C Master 1 base: 0x4002.1000

Offset 0x004

Type RO, reset 0x0000.0000

	reserved										BUSBSY	IDLE	ARBLST	DATAACK	ADRACK	ERROR	BUSY
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	BUSBSY	RO	0	Bus Busy  This bit specifies the state of the I <sup>2</sup> C bus. If set, the bus is busy; otherwise, the bus is idle. The bit changes based on the START and STOP conditions.
5	IDLE	RO	0	I <sup>2</sup> C Idle  This bit specifies the I <sup>2</sup> C controller state. If set, the controller is idle; otherwise the controller is not idle.
4	ARBLST	RO	0	Arbitration Lost  This bit specifies the result of bus arbitration. If set, the controller lost arbitration; otherwise, the controller won arbitration.

Bit/Field	Name	Type	Reset	Description
3	DATAACK	RO	0	Acknowledge Data  This bit specifies the result of the last data operation. If set, the transmitted data was not acknowledged; otherwise, the data was acknowledged.
2	ADRACK	RO	0	Acknowledge Address  This bit specifies the result of the last address operation. If set, the transmitted address was not acknowledged; otherwise, the address was acknowledged.
1	ERROR	RO	0	Error  This bit specifies the result of the last bus operation. If set, an error occurred on the last operation; otherwise, no error was detected. The error can be from the slave address not being acknowledged, the transmit data not being acknowledged, or because the controller lost arbitration.
0	BUSY	RO	0	I <sup>2</sup> C Busy  This bit specifies the state of the controller. If set, the controller is busy; otherwise, the controller is idle. When the <code>BUSY</code> bit is set, the other status bits are not valid.

 Offset 0x004  
 Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	WO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ACK	WO	0	Data Acknowledge Enable  When set, causes received data byte to be acknowledged automatically by the master. See field decoding in Table 16-3 on page 628.
2	STOP	WO	0	Generate STOP  When set, causes the generation of the STOP condition. See field decoding in Table 16-3 on page 628.

Bit/Field	Name	Type	Reset	Description
1	START	WO	0	Generate START When set, causes the generation of a START or repeated START condition. See field decoding in Table 16-3 on page 628.
0	RUN	WO	0	I <sup>2</sup> C Master Enable When set, allows the master to send or receive data. See field decoding in Table 16-3 on page 628.

**Table 16-3. Write Field Decoding for I2CMCS[3:0] Field (Sheet 1 of 3)**

Current State	I2CMSA[0]	I2CMCS[3:0]				Description
	R/S	ACK	STOP	START	RUN	
Idle	0	X <sup>a</sup>	0	1	1	START condition followed by SEND (master goes to the Master Transmit state).
	0	X	1	1	1	START condition followed by a SEND and STOP condition (master remains in Idle state).
	1	0	0	1	1	START condition followed by RECEIVE operation with negative ACK (master goes to the Master Receive state).
	1	0	1	1	1	START condition followed by RECEIVE and STOP condition (master remains in Idle state).
	1	1	0	1	1	START condition followed by RECEIVE (master goes to the Master Receive state).
	1	1	1	1	1	Illegal.
	All other combinations not listed are non-operations.					
Master Transmit	X	X	0	0	1	SEND operation (master remains in Master Transmit state).
	X	X	1	0	0	STOP condition (master goes to Idle state).
	X	X	1	0	1	SEND followed by STOP condition (master goes to Idle state).
	0	X	0	1	1	Repeated START condition followed by a SEND (master remains in Master Transmit state).
	0	X	1	1	1	Repeated START condition followed by SEND and STOP condition (master goes to Idle state).
	1	0	0	1	1	Repeated START condition followed by a RECEIVE operation with a negative ACK (master goes to Master Receive state).
	1	0	1	1	1	Repeated START condition followed by a SEND and STOP condition (master goes to Idle state).
	1	1	0	1	1	Repeated START condition followed by RECEIVE (master goes to Master Receive state).
	1	1	1	1	1	Illegal.
	All other combinations not listed are non-operations.					

Current State	I2CMSA[0]	I2CMCS[3:0]				Description
	R/S	ACK	STOP	START	RUN	
Master Receive	X	0	0	0	1	RECEIVE operation with negative ACK (master remains in Master Receive state).
	X	X	1	0	0	STOP condition (master goes to Idle state). <sup>b</sup>
	X	0	1	0	1	RECEIVE followed by STOP condition (master goes to Idle state).
	X	1	0	0	1	RECEIVE operation (master remains in Master Receive state).
	X	1	1	0	1	Illegal.
	1	0	0	1	1	Repeated START condition followed by RECEIVE operation with a negative ACK (master remains in Master Receive state).
	1	0	1	1	1	Repeated START condition followed by RECEIVE and STOP condition (master goes to Idle state).
	1	1	0	1	1	Repeated START condition followed by RECEIVE (master remains in Master Receive state).
	0	X	0	1	1	Repeated START condition followed by SEND (master goes to Master Transmit state).
	0	X	1	1	1	Repeated START condition followed by SEND and STOP condition (master goes to Idle state).
All other combinations not listed are non-operations.						NOP.

a. An X in a table cell indicates the bit can be 0 or 1.

b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

### Register 3: I<sup>2</sup>C Master Data (I2CMDR), offset 0x008

This register contains the data to be transmitted when in the Master Transmit state, and the data received when in the Master Receive state.

#### I2C Master Data (I2CMDR)

7:0	TPR	R/W	0x1	SCL Clock Period

This field specifies the period of the SCL clock.

$$SCL\_PRD = 2 * (1 + TPR) * (SCL\_LP + SCL\_HP) * CLK\_PRD$$

where:

SCL\_PRD is the SCL line period (I<sup>2</sup>C clock).

TPR is the Timer Period register value (range of 1 to 255).

SCL\_LP is the SCL Low period (fixed at 6).

SCL\_HP is the SCL High period (fixed at 4).

## Register 5: I<sup>2</sup>C Master Interrupt Mask (I2CMIMR), offset 0x010

This register controls whether a raw interrupt is promoted to a controller interrupt.

### I2C Master Interrupt Mask (I2CMIMR)

I2C Master 0 base: 0x4002.0000

I2C Master 1 base: 0x4002.1000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	MIS	RO	0	Masked Interrupt Status  This bit specifies the raw interrupt state (after masking) of the I <sup>2</sup> C master block. If set, an interrupt was signaled; otherwise, an interrupt has not been generated since the bit was last cleared.

## Register 8: I<sup>2</sup>C Master Interrupt Clear (I2CMICR), offset 0x01C

This register clears the raw interrupt.

### I2C Master Interrupt Clear (I2CMICR)

I2C Master 0 base: 0x4002.0000

I2C Master 1 base: 0x4002.1000

Offset 0x01C

Type WO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved															IC	
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	WO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	IC	WO	0	Interrupt Clear  This bit controls the clearing of the raw interrupt. A write of 1 clears the interrupt; otherwise, a write of 0 has no affect on the interrupt state. A read of this register returns no meaningful data.

## Register 9: I<sup>2</sup>C Master Configuration (I2CMCR), offset 0x020

This register configures the mode (Master or Slave) and sets the interface for test mode loopback.

### I2C Master Configuration (I2CMCR)

I2C Master 0 base: 0x4002.0000

I2C Master 1 base: 0x4002.1000

Offset 0x020

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SFE	R/W	0	I <sup>2</sup> C Slave Function Enable  This bit specifies whether the interface may operate in Slave mode. If set, Slave mode is enabled; otherwise, Slave mode is disabled.
4	MFE	R/W	0	I <sup>2</sup> C Master Function Enable  This bit specifies whether the interface may operate in Master mode. If set, Master mode is enabled; otherwise, Master mode is disabled and the interface clock is disabled.
3:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	LPBK	R/W	0	I <sup>2</sup> C Loopback  This bit specifies whether the interface is operating normally or in Loopback mode. If set, the device is put in a test mode loopback configuration; otherwise, the device operates normally.

## 16.6 Register Descriptions (I<sup>2</sup>C Slave)

The remainder of this section lists and describes the I<sup>2</sup>C slave registers, in numerical order by address offset. See also “Register Descriptions (I<sup>2</sup>C Master)” on page 624.

## Register 10: I<sup>2</sup>C Slave Own Address (I2CSOAR), offset 0x000

This register consists of seven address bits that identify the Stellaris<sup>®</sup> I<sup>2</sup>C device on the I<sup>2</sup>C bus.

### I2C Slave Own Address (I2CSOAR)

I2C Slave 0 base: 0x4002.0800

I2C Slave 1 base: 0x4002.1800

Offset 0x000

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	OAR	R/W	0x00	I <sup>2</sup> C Slave Own Address This field specifies bits A6 through A0 of the slave address.

### Register 11: I<sup>2</sup>C Slave Control/Status (I2CCSR), offset 0x004

This register accesses one control bit when written, and three status bits when read.

The read-only Status register consists of three bits: the `FBR`, `RREQ`, and `TREQ` bits. The `First Byte Received (FBR)` bit is set only after the Stellaris<sup>®</sup> device detects its own slave address and receives the first data byte from the I<sup>2</sup>C master. The `Receive Request (RREQ)` bit indicates that the Stellaris<sup>®</sup> I<sup>2</sup>C device has received a data byte from an I<sup>2</sup>C master. Read one data byte from the **I<sup>2</sup>C Slave Data (I2CSDR)** register to clear the `RREQ` bit. The `Transmit Request (TREQ)` bit indicates that the Stellaris<sup>®</sup> I<sup>2</sup>C device is addressed as a Slave Transmitter. Write one data byte into the **I<sup>2</sup>C Slave Data (I2CSDR)** register to clear the `TREQ` bit.

The write-only Control register consists of one bit: the `DA` bit. The `DA` bit enables and disables the Stellaris<sup>®</sup> I<sup>2</sup>C slave operation.

31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	FBR	RO	0	<p>First Byte Received</p> <p>Indicates that the first byte following the slave's own address is received. This bit is only valid when the <code>RREQ</code> bit is set, and is automatically cleared when data has been read from the <b>I2CSDR</b> register.</p> <p><b>Note:</b> This bit is not used for slave transmit operations.</p>
1	TREQ	RO	0	<p>Transmit Request</p> <p>This bit specifies the state of the I<sup>2</sup>C slave with regards to outstanding transmit requests. If set, the I<sup>2</sup>C unit has been addressed as a slave transmitter and uses clock stretching to delay the master until data has been written to the <b>I2CSDR</b> register. Otherwise, there is no outstanding transmit request.</p>

Bit/Field	Name	Type	Reset	Description
0	RREQ	RO	0	Receive Request

This bit specifies the status of the I<sup>2</sup>C slave with regards to outstanding receive requests. If set, the I<sup>2</sup>C unit has outstanding receive data from the I<sup>2</sup>C master and uses clock stretching to delay the master until the data has been read from the **I2CSDR** register. Otherwise, no receive data is outstanding.

2	STOPIC	WO	0	Stop Condition Interrupt Clear  This bit controls the clearing of the raw interrupt for stop condition detect. When set, it clears the STOPRIS interrupt bit; otherwise, it has no effect on the STOPRIS bit value.
1	STARTIC	WO	0	Start Condition Interrupt Clear  This bit controls the clearing of the raw interrupt for start condition detect. When set, it clears the STARTRIS interrupt bit; otherwise, it has no effect on the STARTRIS bit value.
0	DATAIC	WO	0	Data Interrupt Clear  This bit controls the clearing of the raw interrupt for data received and data requested. When set, it clears the DATARIS interrupt bit; otherwise, it has no effect on the DATARIS bit value.

## 17 Inter-Integrated Circuit Sound (I<sup>2</sup>S) Interface

The I<sup>2</sup>S module is a configurable serial audio core that contains a transmit module and a receive module. The module is configurable for the I<sup>2</sup>S as well as Left-Justified and Right-Justified serial audio formats. Data can be in one of four modes: Stereo, Mono, Compact 16-bit Stereo and Compact 8-Bit Stereo.

The transmit and receive modules each have an 8-entry audio-sample FIFO. An audio sample can consist of a Left and Right Stereo sample, a Mono sample, or a Left and Right Compact Stereo sample. In Compact 16-Bit Stereo, each FIFO entry contains both the 16-bit left and 16-bit right samples, allowing efficient data transfers and requiring less memory space. In Compact 8-bit Stereo, each FIFO entry contains an 8-bit left and an 8-bit right sample, reducing memory requirements further.

Both the transmitter and receiver are capable of being a master or a slave.

The Stellaris<sup>®</sup> I<sup>2</sup>S module has the following features:

- Configurable audio format supporting I<sup>2</sup>S, Left-justification, and Right-justification
- Configurable sample size from 8 to 32 bits
- Mono and Stereo support
- 8-, 16-, and 32-bit FIFO interface for packing memory
- Independent transmit and receive 8-entry FIFOs
- Configurable FIFO-level interrupt and  $\mu$ DMA requests
- Independent transmit and receive MCLK direction control
- Transmit and receive internal MCLK sources
- Independent transmit and receive control for serial clock and word select
- MCLK and SCLK can be independently set to master or slave
- Configurable transmit zero or last sample when FIFO empty
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Burst requests
  - Channel requests asserted when FIFO contains required amount of data

## 17.1 Block Diagram

Figure 17-1. I<sup>2</sup>S Block Diagram

## 17.2 Functional Description

The Inter-Integrated Circuit Sound (I<sup>2</sup>S) module contains separate transmit and receive engines. Each engine consists of the following:

- Serial encoder for the transmitter; serial decoder for the receiver
- 8-entry FIFO to store sample data
- Independent configuration of all programmable settings

The basic programming model of the I<sup>2</sup>S block is as follows:

- Configuration
  - Overall I<sup>2</sup>S module configuration in the **I<sup>2</sup>S Module Configuration (I2SCFG)** register. This register is used to select the MCLK source and enable the receiver and transmitter.

- Transmit and receive configuration in the **I<sup>2</sup>S Transmit Module Configuration (I2STXCFG)** and **I<sup>2</sup>S Receive Module Configuration (I2SRXCFG)** registers. These registers set the basic parameters for the receiver and transmitter such as data configuration (justification, delay, read mode, sample size, and system data size); SCLK (polarity and source); and word select polarity.
- Transmit and receive FIFO configuration in the **I<sup>2</sup>S Transmit FIFO Configuration (I2STXFIFOCFG)** and **I<sup>2</sup>S Receive FIFO Configuration (I2SRXFIFOCFG)** registers. These registers select the Compact Stereo mode size (16-bit or 8-bit), provide indication of whether the next sample is Left or Right, and select mono mode for the receiver.
- FIFO
  - Transmit and receive FIFO data in the **I<sup>2</sup>S Transmit FIFO Data (I2STXFIFO)** and **I<sup>2</sup>S Receive FIFO Data (I2SRXFIFO)** registers
  - Information on FIFO data levels in the **I<sup>2</sup>S Transmit FIFO Level (I2STXLEV)** and **I<sup>2</sup>S Receive FIFO Level (I2SRXLEV)** registers
  - Configuration for FIFO service requests based on FIFO levels in the **I<sup>2</sup>S Transmit FIFO Limit (I2STXLIMIT)** and **I<sup>2</sup>S Receive FIFO Limit (I2SRXLIM)** registers
- Interrupt Control
  - Interrupt masking configuration in the **I<sup>2</sup>S Interrupt Mask (I2SIM)** register
  - Raw and masked interrupt status in the **I<sup>2</sup>S Raw Interrupt Status (I2SRIS)** and **I<sup>2</sup>S Masked Interrupt Status (I2SMIS)** registers
  - Interrupt clearing through the **I<sup>2</sup>S Interrupt Clear (I2SIC)** register
  - Configuration for FIFO service requests interrupts and transmit/receive error interrupts in the **I<sup>2</sup>S Transmit Interrupt Status and Mask (I2STXISM)** and **I<sup>2</sup>S Receive Interrupt Status and Mask (I2SRXISM)** registers

Figure 17-2 on page 648 provides an example of an I<sup>2</sup>S data transfer. Figure 17-3 on page 648 provides an example of an Left-Justified data transfer. Figure 17-4 on page 648 provides an example of an Right-Justified data transfer.

Figure 17-2. I<sup>2</sup>S Data Transfer

Figure 17-3. Left-Justified Data Transfer

Figure 17-4. Right-Justified Data Transfer

## 17.2.1 Transmit

The transmitter consists of a serial encoder, an 8-entry FIFO, and control logic. The transmitter has independent MCLK (I2S0TXMCLK), SCLK (I2S0TXSCK), and Word-Select (I2S0TXWS) signals.

### 17.2.1.1 Serial Encoder

The serial encoder reads audio samples from the receive FIFO and converts them into an audio stream. By configuring the serial encoder, common audio formats I<sup>2</sup>S, Left-Justified, and Right-Justified are supported. The MSB is transmitted first. The sample size and system data size are configurable with the SSZ and SDSZ bits in the I<sup>2</sup>S Transmit Module Configuration (I2STXCFG) register. The sample size is the number of bits of data being transmitted, and the system data size is the number of I2S0TXSCK transitions between the word select transitions. The system data size must be large enough to accommodate the maximum sample size. In Mono mode, the sample data is repeated in both the left and right channels. When the FIFO is empty, the user may select either

transmission of zeros or of the last sample. The serial encoder is enabled using the `TXEN` bit in the **I<sup>2</sup>S Module Configuration (I2SCFG)** register.

### 17.2.1.2 FIFO Operation

The transmit FIFO stores eight Mono samples or eight Stereo sample-pairs of data and is accessed through the **I<sup>2</sup>S Transmit FIFO Data (I2STXFIFO)** register. The FIFO interface for the audio data is different based on the Write mode, defined by the **I<sup>2</sup>S Transmit FIFO Configuration (I2STXFIFOCFG)** Compact Stereo Sample Size bit (`CSS`) and the **I2STXCFG** Write Mode field (`WM`). All data samples are MSB-aligned. Table 17-1 on page 649 defines the interface for each Write mode. Stereo samples are written first left then right. The next sample (right or left) to be written is indicated by the `LRS` bit in the **I2STXFIFOCFG** register.

**Table 17-1. I<sup>2</sup>S Transmit FIFO Interface**

<code>WM</code> field in <b>I2STXCFG</b>	<code>CSS</code> bit in <b>I2STXFIFOCFG</b>	Write Mode	Sample Width	Samples per FIFO Write	Data Alignment
0x0	don't care	Stereo	8-32 bits	1	MSB
0x1	0	Compact Stereo - 16 bit	8-16 bits	2	MSB Right [31:16], Left [15:0]
0x1	1	Compact Stereo - 8 bit	8 bits	2	Right [15:8], Left[7:0]
0x2	don't care	Mono	8-32 bits	1	MSB

The number of samples in the transmit FIFO can be read using the **I<sup>2</sup>S Transmit FIFO Level (I2STXLEV)** register. The value ranges from 0 to 16. Stereo and compact stereo sample pairs are counted as two. The mono samples also increment the count by two, therefore, four mono samples will have a count of eight.

### 17.2.1.3 Clock Control

The transmitter `MCLK` and `SCLK` can be independently programmed to be the master or slave. The transmitter is programmed to be the master or slave of the `SCLK` using the `MSL` bit in the **I2STXCFG** register. When the transmitter is the master, the `I2S0TXSCK` frequency is the specified `I2S0TXMCLK` divided by four. The `I2S0TXSCK` may be inverted using the `SCP` bit in the **I2STXCFG** register.

The transmitter can also be the master or slave of the `MCLK`. When the transmitter is the master, the PLL must be active and a fractional clock divider must be programmed. See page 129 for the setup for the master `I2S0TXMCLK` source. An external transmit `I2S0TXMCLK` is selected using the `TXSLV` bit in the **I2SCFG** register.

The following tables show combinations of the `TXINT` and `TXFRAC` bits in the **I<sup>2</sup>S MCLK Configuration (I2SMCLKCFG)** register that provide `MCLK` frequencies within acceptable error limits. In the table, `Fs` is the sampling frequency in kHz and possible crystal frequencies are shown in MHz across the top row of the table. The words "not supported" in the table mean that it is not possible to obtain the specified sampling frequencies with the specified crystal frequency within the error tolerance of 0.3%. The values in the table are based on the following values:

$$\text{MCLK} = F_s * 256$$

$$\text{VCO} = 400 \text{ MHz}$$

The Integer value is taken from the result of the following calculation:

$$\text{ROUND}(\text{VCO}/\text{MCLK})$$

The remaining fractional component is converted to binary, and the first four bits are the Fractional value.

**Table 17-2. Crystal Frequency (Values from 3.5795 MHz to 5 MHz)**

Fs (kHz)	Crystal Frequency (MHz)

192	8	2	8	0

#### 17.2.1.4 Interrupt Control

There is one I<sup>2</sup>S interrupt to the CPU. The interrupt is asserted to the CPU whenever any of the transmit or receive sources is asserted. The transmit module has two interrupt sources: the FIFO service request and write error. The interrupts may be masked using the **TXFSR** and **TXWE** bits in the **I<sup>2</sup>S Interrupt Mask (I2SIM)** register. The status of the interrupt source is indicated by the **I<sup>2</sup>S Raw Interrupt Status (I2SRIS)** register. The status of enabled interrupts is indicated by the **I<sup>2</sup>S Masked Interrupt Status (I2SMIS)** register. The FIFO level interrupt has a second level of masking using the **FFM** bit in the **I<sup>2</sup>S Transmit Interrupt Status and Mask (I2STXISM)** register.

The FIFO service request interrupt is asserted when the FIFO level (indicated by the **LEVEL** field in the **I<sup>2</sup>S Transmit FIFO Level (I2STXLEV)** register) is below the FIFO limit (programmed using the **I<sup>2</sup>S Transmit FIFO Limit (I2STXLIMIT)** register) and both the **TXFSR** and **FFM** bits are set. If software attempts to write to a full FIFO, a Transmit FIFO Write error occurs (indicated by the **TXWE** bit in the **I<sup>2</sup>S Raw Interrupt Status (I2SRIS)** register). The **TXWE** bit in the **I2SRIS/I2SMIS** registers is cleared by setting the **TXWE** bit in the **I<sup>2</sup>S Interrupt Clear (I2SIC)** register.

#### 17.2.1.5 DMA Support

The  $\mu$ DMA can be used to more efficiently stream data to and from the I<sup>2</sup>S bus. The FIFO Interrupt Mask bit (**FFM**) in the **I2STXISM** register must be set for the request signaling to propagate to the  $\mu$ DMA module. See “Micro Direct Memory Access ( $\mu$ DMA)” on page 226 for channel configuration.

The I<sup>2</sup>S module uses the  $\mu$ DMA burst request signal, not the single request. Thus each time a  $\mu$ DMA request is made, the  $\mu$ DMA controller transfers the number of items specified as the burst size for the  $\mu$ DMA channel. Therefore, the  $\mu$ DMA channel burst size and the I<sup>2</sup>S FIFO service request limit must be set to the same value (using the **LIMIT** field in the **I2STXLIMIT** register).

### 17.2.2 Receive

#### 17.2.2.1 Serial Decoder

The serial decoder accepts incoming audio stream data and places the sample data in the receive FIFO. By configuring the serial decoder, common audio formats I<sup>2</sup>S, Left-Justified, and Right-Justified are supported. The MSB is transmitted first. The sample size and system data size are configurable with the **SSZ** and **SDSZ** bits in the **I<sup>2</sup>S Receive Module Configuration (I2SRXCFG)** register. The sample size is the number of bits of data being received, and the system data size is the number of **I2S0TXSCK** transitions between the word select transitions. The system data size must be large enough to accommodate the maximum sample size. Any bits received after the LSB are 0s. If the FIFO is full, the incoming sample (in Mono) or sample-pairs (Stereo) are dropped until the FIFO has space. The serial decoder is enabled using the **RXEN** bit in the **I2SCFG** register.

#### 17.2.2.2 FIFO Operation

The receive FIFO stores eight Mono samples or eight Stereo sample-pairs of data and is accessed through the **I<sup>2</sup>S Receive FIFO Data (I2SRXFIFO)** register. Table 17-6 on page 653 defines the interface for each Read mode. All data is stored MSB-aligned. The Stereo data is read left sample then right.

In Mono mode, the FIFO interface can be configured to read the right or left channel by setting the FIFO Mono Mode bit (**FMM**) in the **I<sup>2</sup>S Receive FIFO Configuration (I2SRXFIFOCFG)** register. This enables reads from a single channel, where the channel selected can be either the right or left as determined by the **LRS** bit in the **I2SRXFIFOCFG** register.

Table 17-6. I<sup>2</sup>S Receive FIFO Interface

RM bit in I2RXCFG	CSS bit in I2SRXFIFOCFG	Read Mode	Sample Width	Samples per FIFO Write	Data Alignment
0	don't care	Stereo	8-32 bits	1	MSB
1	0	Compact Stereo - 16 bit	8-16 bits	2	MSB Right [31:15], Left [15:0]
1	1	Compact Stereo - 8 bit	8 bits	2	Right [15:8] Left[7:0]
0	don't care	Mono (FMM bit in the I2SRXFIFOCFG register must be set.)	8-32 bits	1	MSB

The number of samples in the receive FIFO can be read using the **I<sup>2</sup>S Receive FIFO Level (I2SRXLEV)** register. The value ranges from 0 to 16. Stereo and compact stereo sample pairs are counted as two. The mono samples also increment the count by two, therefore four Mono samples will have a count of eight.

### 17.2.2.3 Clock Control

The receiver MCLK and SCLK can be independently programmed to be the master or slave. The receiver is programmed to be the master or slave of the SCLK using the MSL bit in the **I2SRXCFG** register. When the receiver is the master, the I2S0RXSCK frequency is the specified I2S0RXMCLK divided by four. The I2S0RXSCK may be inverted using the SCP bit in the **I2SRXCFG** register.

The receiver can also be the master or slave of the MCLK. When the receiver is the master, the PLL must be active and a fractional clock divider must be programmed. See page 129 for the setup for the master I2S0RXMCLK source. An external transmit I2S0RXMCLK is selected using the RXSLV bit in the **I2SCFG** register.

Refer to "Clock Control" on page 649 for combinations of the RXINT and RXFRAC bits in the **I<sup>2</sup>S MCLK Configuration (I2SMCLKCFG)** register that provide MCLK frequencies within acceptable error limits. In the table, Fs is the sampling frequency in kHz and possible crystal frequencies are shown in MHz across the top row of the table. The words "not supported" in the table mean that it is not possible to obtain the specified sampling frequencies with the specified crystal frequency within the error tolerance of 0.3%.

### 17.2.2.4 Interrupt Control

There is one I<sup>2</sup>S interrupt to the CPU. The interrupt is asserted to the CPU whenever any of the transmit or receive sources is asserted. The receive module has two interrupt sources: the FIFO service request and read error. The interrupts may be masked using the RXFSR and RXRE bits in the **I2SIM** register. The status of the interrupt source is indicated by the **I2SRIS** register. The status of enabled interrupts is indicated by the **I2SMIS** register. The FIFO service request interrupt has a second level of masking using the FFM bit in the **I<sup>2</sup>S Receive Interrupt Status and Mask (I2SRXISM)** register. The sources may be masked using the **I2SIM** register.

The FIFO service request interrupt is asserted when the FIFO level (indicated by the LEVEL field in the **I<sup>2</sup>S Receive FIFO Level (I2SRXLEV)** register) is above the FIFO limit (programmed using the **I<sup>2</sup>S Receive FIFO Limit (I2SRXLIMIT)** register) and both the RXFSR and FFM bits are set. An error occurs when reading an empty FIFO or if a stereo sample pair is not read left then right. To clear an interrupt, write a 1 to the appropriate bit in the **I2SIC** register. If software attempts to read an empty FIFO or if a stereo sample pair is not read left then right, a Receive FIFO Read error occurs (indicated by the RXRE bit in the **I2SRIS** register). The RXRE bit in the **I2SRIS/I2SMIS** registers is cleared by setting the RXRE bit in the **I2SIC** register.

### 17.2.2.5 DMA Support

The  $\mu$ DMA can be used to more efficiently stream data to and from the I<sup>2</sup>S bus. The FIFO Interrupt Mask bit (**FFM**) in the **I2SRXISM** register must be set for the request signaling to propagate to the  $\mu$ DMA module. See “Micro Direct Memory Access ( $\mu$ DMA)” on page 226 for channel configuration.

The I<sup>2</sup>S module uses the  $\mu$ DMA burst request signal, not the single request. Thus each time a  $\mu$ DMA request is made, the  $\mu$ DMA controller transfers the number of items specified as the burst size for the  $\mu$ DMA channel. Therefore, the  $\mu$ DMA channel burst size and the I<sup>2</sup>S FIFO service request limit must be set to the same value (using the **LIMIT** field in the **I2SRXLIMIT** register).

## 17.3 Initialization and Configuration

The default setup for the I<sup>2</sup>S transmit and receive is to be using external MCLK, external SCLK, Stereo, I<sup>2</sup>S audio format, and 32-bit data samples. The following example shows how to configure a system using the internal MCLK, internal SCLK, Compact Stereo, and Left-Justified audio format with 16-bit data samples.

1. Enable the I<sup>2</sup>S peripheral clock by writing a value of 0x1000.0000 to the **RCGC1** register in the System Control module. See page 167.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. See page 311.
4. Set up the MCLK sources for a 48-kHz sample rate. The input crystal is assumed to be 6 MHz for this example (internal source).
  - Enable the PLL by clearing the **PWRDWN** bit in the **RCC** register in the System Control module. See page 113.
  - Set the MCLK dividers and enable them by writing 0x0208.0208 to the **I2SMCLKCFG** register in the System Control module. See page 129.
  - Enable the MCLK internal sources by writing 0x8208.8208 to the **I2SMCLKCFG** register in the System Control module.

To allow an external MCLK to be used, set bits 4 and 5 of the **I2SCFG** register. Starting up the PLL and enabling the MCLK sources is not required.

5. Set up the Serial Bit Clock SCLK source. By default, the SCLK is externally sourced.
  - Receiver: Masters the **I2S0RXSCK** by ORing 0x0040.0000 into the **I2SRXCFCG** register.
  - Transmitter: Masters the **I2S0TXSCK** by ORing 0x0040.0000 into the **I2STXCFCG** register.
6. Configure the Serial Encoder/Decoder (Left-Justified, Compact Stereo, 16-bit samples, 32-bit system data size).
  - Set the audio format using the Justification (**JST**), Data Delay (**DLY**), SCLK polarity (**SCP**), and Left-Right Polarity (**LRP**) bits written to the **I2STXCFCG** and **I2SRXCFCG** registers. The settings are shown in the table below.

**Table 17-7. Audio Formats Configuration**

Audio Format	I2STXCFG/I2SRXCFG Register Bit			
	JST	DLY	SCP	LRP
I <sup>2</sup> S	0	1	0	1
Left-Justified	0	0	0	0
Right-Justified	1	0	0	0

- Write 0x0140.3DF0 to both the **I2STXCFG** and **I2SRXCFG** registers to program the following configurations:
  - Set the sample size to 16 bits using the **SSZ** field of the **I2STXCFG** and **I2SRXCFG** registers.
  - Set the system data size to 32 bits using the **SDSZ** field of the **I2STXCFG** and **I2SRXCFG** registers.
  - Set the Write and Read modes using the **WM** and **RM** fields in the **I2STXCFG** and **I2SRXCFG** registers, respectively.
- 7. Set up the FIFO limits for triggering interrupts (also used for  $\mu$ DMA)
  - Set up the transmit FIFO to trigger when it has less than four sample pairs by writing a 0x0000.0008 to the **I2STXLIMIT** register.
  - Set up the receive FIFO to trigger when there are more than four sample pairs by writing a 0x0000.00008 to the **I2SRXLIMIT** register.
- 8. Enable interrupts.
  - Enable the transmit FIFO interrupt by setting the **FFM** bit in the **I2STXISM** register (write 0x0000.0001).
  - Set up the receive FIFO interrupts by setting the **FFM** bit in the **I2SRXISM** register (write 0x0000.0001).
  - Enable the TX FIFO service request, the TX Error, the RX FIFO service request, and the RX Error interrupts to be sent to the CPU by writing a 0x0000.0033 to the **I2SSIM** register.
- 9. Enable the Serial Encoder and Serial Decoders by writing a 0x0000.0003 to the **I2SCFG** register.

## 17.4 Register Map

Table 17-8 on page 655 lists the I<sup>2</sup>S registers. The offset listed is a hexadecimal increment to the register's address, relative to the I<sup>2</sup>S interface base address of 0x4005.4000. Note that the I<sup>2</sup>S module clock must be enabled before the registers can be programmed (see page 167).

**Table 17-8. Inter-Integrated Circuit Sound (I<sup>2</sup>S) Interface Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	I2STXFIFO	WO	0x0000.0000	I2S Transmit FIFO Data	657

0xC1C	I2SIC	WO	0x0000.0000	I2S Interrupt Clear	676

## 17.5 Register Descriptions

The remainder of this section lists and describes the I<sup>2</sup>S registers, in numerical order by address offset.

## Register 1: I<sup>2</sup>S Transmit FIFO Data (I2STXFIFO), offset 0x000

This register is the 32-bit serial audio transmit data register. In Stereo mode, the data is written left, right, left, right, and so on. The `LRS` bit in the **I<sup>2</sup>S Transmit FIFO Configuration (I2STXFIFOCFG)** register can be read to verify the next position expected. In Compact 16-bit mode, bits [31:16] contain the right sample, and bits [15:0] contain the left sample. In Compact 8-bit mode, bits [15:8] contain the right sample, and bits [7:0] contain the left sample. In Mono mode, each 32-bit entry is a single sample.

Note that if the FIFO is full and a write is attempted, a transmit FIFO write error is generated.

## Register 2: I<sup>2</sup>S Transmit FIFO Configuration (I2STXFIFOCFG), offset 0x004

This register configures the sample for dual-channel operation. In Stereo mode, the LRS bit toggles between left and right samples as the Transmit FIFO is written. The left sample is written first, followed by the right.

### I2S Transmit FIFO Configuration (I2STXFIFOCFG)

Base 0x4005.4000  
 Offset 0x004  
 Type R/W, reset 0x0000.0000

## Register 6: I<sup>2</sup>S Transmit FIFO Level (I2STXLEV), offset 0x018

The number of samples in the transmit FIFO can be read using the **I2STXLEV** register. The value ranges from 0 to 16. Stereo and Compact Stereo sample-pairs are counted as two. Mono samples also increment the count by two. For example, the LEVEL field is set to eight if there are four Mono samples.

### I<sup>2</sup>S Transmit FIFO Level (I2STXLEV)

31:5	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4:0	LEVEL	RO	0x00	Number of Audio Samples This field contains the number of samples in the FIFO.

### Register 7: I<sup>2</sup>S Receive FIFO Data (I2SRXFIFO), offset 0x800

This register is the 32-bit serial audio receive data register. In Stereo mode, the data is read left, right, left, right, and so on. The *LRS* bit in the **I<sup>2</sup>S Receive FIFO Configuration (I2SRXFIFOCFG)** register can be read to verify the next position expected. In Compact 16-bit mode, bits [31:16] contain the right sample, and bits [15:0] contain the left sample. In Compact 8-bit mode, bits [15:8] contain the right sample, and bits [7:0] contain the left sample. In Mono mode, each 32-bit entry is a single sample. If the FIFO is empty, a read of this register returns a value of 0x0000.0000 and generates a receive FIFO read error.

#### I2S Receive FIFO Data (I2SRXFIFO)

Base 0x4005.4000  
 Offset 0x800  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	RXFIFO	RO	0x0000.0000	RX Data

Serial audio sample data received.

The read of an empty FIFO will return a value of 0x0.

## Register 8: I<sup>2</sup>S Receive FIFO Configuration (I2SRXFIFOCFG), offset 0x804

This register configures the sample for dual-channel operation. In Stereo mode, the LRS bit toggles between Left and Right as the samples are read from the receive FIFO. In Mono mode, both the left and right samples are stored in the FIFO. The FMM bit can be used to read only the left or right sample as determined by the LRP bit. In Compact Stereo 8- or 16-bit mode, both the left and right samples are read in one access from the FIFO.

31:6	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	RXSLV	R/W	0	Use External I2S0RXMCLK  When set, this bit configures the receiver to use the externally driven I2S0RXMCLK signal.  When clear, this bit configures the receiver to use the internally generated MCLK as the I2S0RXMCLK signal. See "Clock Control" on page 649 for information on how to program the I2S0RXMCLK.
4	TXSLV	R/W	0	Use External I2S0TXMCLK  When set, this bit configures the transmitter to use the externally driven I2S0TXMCLK signal.  When clear, this bit configures the transmitter to use the internally generated MCLK as the I2S0TXMCLK signal. See "Clock Control" on page 649 for information on how to program the I2S0TXMCLK.
3:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	RXEN	R/W	0	Serial Receive Engine Enable  When clear, this bit disables the serial receive engine.  When set, this bit enables the serial receive engine.
0	TXEN	R/W	0	Serial Transmit Engine Enable  When clear, this bit disables the serial transmit engine.  When set, this bit enables the serial transmit engine.

### Register 14: I<sup>2</sup>S Interrupt Mask (I2SIM), offset 0xC10

This register masks the interrupts to the CPU.

#### I2S Interrupt Mask (I2SIM)

Base 0x4005.4000  
 Offset 0xC10  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	RXRE	R/W	0	Receive FIFO Read Error  When clear, this bit causes the receive FIFO read error interrupt to be masked and not sent to the CPU.  When set, this bit allows the receive FIFO read error interrupt to be sent to the CPU.
4	RXFSR	R/W	0	Receive FIFO Service Request  When clear, this bit causes the receive FIFO service request interrupt to be masked and not sent to the CPU.  When set, this bit allows the receive FIFO service request interrupt to be sent to the CPU.
3:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	TXWE	R/W	0	Transmit FIFO Write Error  When clear, this bit causes the transmit FIFO write error interrupt to be masked and not sent to the CPU.  When set, this bit allows the transmit FIFO write error interrupt to be sent to the CPU.
0	TXFSR	R/W	0	Transmit FIFO Service Request  When clear, this bit causes the transmit FIFO service request interrupt to be masked and not sent to the CPU.  When set, this bit allows the transmit FIFO service request interrupt to be sent to the CPU.

## Register 15: I<sup>2</sup>S Raw Interrupt Status (I2SRIS), offset 0xC14

This register reads the unmasked interrupt status.

### I2S Raw Interrupt Status (I2SRIS)

0	reserved	WO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## 18 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

Each Stellaris<sup>®</sup> CAN controller supports the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CAN<sub>n</sub>TX and CAN<sub>n</sub>RX signals

## 18.1 Block Diagram

Figure 18-1. CAN Controller Block Diagram

## 18.2 Functional Description

The Stellaris<sup>®</sup> CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 18-2 on page 679.

**Figure 18-2. CAN Data/Remote Frame**

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the Stellaris<sup>®</sup> memory map, so the Stellaris<sup>®</sup> CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. As there is no direct access to the message object memory, these two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

### 18.2.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 158). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.

Software initialization is started by setting the **INIT** bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While **INIT** is set, all message transfers to and from the CAN bus are stopped and the **CANnTX** signal is held High. Entering the initialization state does not change

the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the `MSGVAL` bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the `INIT` and `CCE` bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the `INIT` bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the `MSGVAL` bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the `MSGVAL` bit again to indicate that the message object is once again valid.

## 18.2.2 Operation

There are two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**), which are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the `INIT` bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the `MNUM` bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the `MSK` bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. These can be message objects used for one-time data transfers, or permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate `TXRQST` bit in the **CAN Transmission Request n (CANTXRQn)** register and the `NEWDAT` bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (`MNUM`) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started.

Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the `RMTEN` bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the `TXRQST` bit to be set and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. This can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The `MXTD` bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

### 18.2.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if there is no data transfer occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's `NEWDAT` bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the `TXRQST` bit in the **CANTXRQn** register is cleared. If the CAN controller is set up to interrupt upon a successful transmission of a message object, (the `TXIE` bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the `INTPND` bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

### 18.2.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
  - Set the `WRNRD` bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the `IDMASK`, `DIR`, and `MXTD` of the message object into the **CAN IFn** registers using the `MASK` bit
  - Specify whether to transfer the `ID`, `DIR`, `XTD`, and `MSGVAL` of the message object into the interface registers using the `ARB` bit
  - Specify whether to transfer the control bits into the interface registers using the `CONTROL` bit
  - Specify whether to clear the `INTPND` bit in the **CANIFnMCTL** register using the `CLRINTPND` bit
  - Specify whether to clear the `NEWDAT` bit in the **CANNWDAn** register using the `NEWDAT` bit
  - Specify which bits to transfer using the `DATAA` and `DATAB` bits
2. In the **CANIFnMSK1** register, use the `MSK[15:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[15:0]` in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit

identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.

3. In the **CANIFnMSK2** register, use the `MSK[12:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[12:0]` are used for bits [28:16] of the 29-bit message identifier; whereas `MSK[12:2]` are used for bits [10:0] of the 11-bit message identifier. Use the `MXTD` and `MDIR` bits to specify whether to use `XTD` and `DIR` for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure `ID[15:0]` in the **CANIFnARB1** register to be used for bits [15:0] of the message identifier and `ID[12:0]` in the **CANIFnARB2** register to be used for bits [28:16] of the message identifier. Set the `XTD` bit to indicate an extended identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure `ID[12:2]` in the **CANIFnARB2** register to be used for bits [10:0] of the message identifier. Clear the `XTD` bit to indicate a standard identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:
  - Optionally set the `UMASK` bit to enable the mask (`MSK`, `MXTD`, and `MDIR` specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the `TXIE` bit to enable the `INTPND` bit to be set after a successful transmission
  - Optionally set the `RMTEN` bit to enable the `TXRQST` bit to be set upon the reception of a matching remote frame allowing automatic transmission
  - Set the `EOB` bit for a single message object;
  - Set the `DLC[3:0]` field to specify the size of the data frame. Take care during this configuration not to set the `NEWDAT`, `MSGLST`, `INTPND` or `TXRQST` bits.
7. Load the data to be transmitted into the CAN IFn Data (**CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, **CANIFnDB2**) or (**CANIFnDATAA** and **CANIFnDATAB**) registers. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register.
8. Program the number of the message object to be transmitted in the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register.
9. When everything is properly configured, set the `TXRQST` bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the `RMTEN` bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

### 18.2.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the `MSGVAL` bit in the **CANIFnARB2** register nor the `TXRQST` bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the **WRNRD**, **DATAA** and **DATAB** bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** registers, and then the number of the message object is written to the **MNUM** field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the **TXRQST** bit in the **CANIFnMSKn** register.

To prevent the clearing of the **TXRQST** bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the **NEWDAT** and **TXRQST** bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, **NEWDAT** is cleared as soon as the new transmission has started.

### 18.2.6 Accepting Received Message Objects

When the arbitration and control field (the **ID** and **XTD** bits in the **CANIFnARB2** and the **RMTEN** and **DLC[3:0]** bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the **UMASK** bit in the **CANIFnMCTL** register. Each valid message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

### 18.2.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the **DLC** bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The **NEWDAT** bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the **NEWDAT** bit is already set, the **MSGLST** bit in the **CANIFnMCTL** register is set to indicate that the previous data was lost. If the system requires an interrupt upon successful reception of a frame, the **RXIE** bit of the **CANIFnMCTL** register should be set. In this case, the **INTPND** bit of the same register is set, causing the **CANINT** register to point to the message object that just received a message. The **TXRQST** bit of this message object should be cleared to prevent the transmission of a remote frame.

### 18.2.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

Configuration in CANIFnMCTL	Description
<ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 1 (set the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame to enable transmission)</li> <li>■ UMASK = 1 or 0</li> </ul>	At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.
<ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 0 (ignore mask in the <b>CANIFnMSK<sub>n</sub></b> register)</li> </ul>	At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and there is no indication that the remote frame ever happened.
<ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ RMTEN = 0 (do not change the TXRQST bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the <b>CANIFnMSK<sub>n</sub></b> register) for acceptance filtering)</li> </ul>	At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This is useful for a remote data request from another CAN device for which the Stellaris® controller does not have readily available data. The software must fill the data and answer the frame manually.

### 18.2.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This should not be confused with the message identifier as that priority is enforced by the CAN bus. This means that if message object 1 and message object 2 both have valid messages that need to be transmitted, message object 1 will always be transmitted first regardless of the message identifier in the message object itself.

### 18.2.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 681 section, except that the WRNRD bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 681 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the

acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.

4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 681 section to program `XTD` and `ID` bits for the message identifier to be received; set the `MSGVAL` bit to indicate a valid message; and clear the `DIR` bit to specify receive.
5. In the **CANIFnMCTL** register:
  - Optionally set the `UMASK` bit to enable the mask (`MSK`, `MXTD`, and `MDIR` specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the `RXIE` bit to enable the `INTPND` bit to be set after a successful reception
  - Clear the `RMTEN` bit to leave the `TXRQST` bit unchanged
  - Set the `EOB` bit for a single message object
  - Set the `DLC[3:0]` field to specify the size of the data frame

Take care during this configuration not to set the `NEWDAT`, `MSGLST`, `INTPND` or `TXRQST` bits.

6. Program the number of the message object to be received in the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are received. The `MXTD` bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

### 18.2.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes `0x007F` to the **CANIFnCMSK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the `NEWDAT` and `INTPND` bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The `NEWDAT` bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The `MSGLST` bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object

was read. `MSGLST` is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the `TXRQST` bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the `TXRQST` bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

### 18.2.11.1 Configuration of a FIFO Buffer

With the exception of the `EOB` bit in the `CANIFnMCTL` register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see "Configuring a Receive Message Object" on page 684). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The `EOB` bit of all message objects of a FIFO buffer except the last one must be cleared. The `EOB` bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

### 18.2.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the `NEWDAT` of the `CANIFnMCTL` register bit of this message object is set. By setting `NEWDAT` while `EOB` is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the `NEWDAT` bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects has been released by clearing the `NEWDAT` bit, all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer and therefore overwrite previous messages.

### 18.2.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the `CANIFnCRQ` register, the `TXRQST` and `CLRINTPND` bits in the `CANIFnCMSK` register should be set such that the `NEWDAT` and `INTPEND` bits in the `CANIFnMCTL` register are cleared after the read. The values of these bits in the `CANIFnMCTL` register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. Figure 18-3 on page 687 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 18-3. Message Objects in a FIFO Buffer

## 18.2.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's **INTPND** bit in the **CANIFnMCTL** register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier **INTID** in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as 0x0000. If the value of the **INTID** field is different from 0, then there is an interrupt pending. If the **IE** bit is set in the **CANCTL** register, the interrupt line to the CPU is active. The interrupt line remains active until the **INTID** field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until **IE** is cleared, which disables interrupts from the CAN controller.

The **INTID** field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The **SIE** bit in the **CANCTL** register controls whether a change of the **RXOK**, **TXOK**, and **LEC** bits in the **CANSTS** register can cause an interrupt. The **EIE** bit in the **CANCTL** register controls whether a change of the **BOFF** and **EWARN** bits in the **CANSTS** register can cause an interrupt. The **IE** bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the microcontroller's interrupt controller. The **CANINT** register is updated even when the **IE** bit in the **CANCTL** register is clear, but the interrupt will not be indicated to the CPU.

A value of 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the **RXOK**, **TXOK**, and **LEC** bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

There are two ways to determine the source of an interrupt during interrupt handling. The first is to read the **INTID** bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's **INTPND** bit at the same time by setting the **CLRINTPND** bit in the **CANIFnCMSK** register. Once the **INTPND** bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

## 18.2.13 Test Mode

A Test Mode is provided, which allows various diagnostics to be performed. Test Mode is entered by setting the **TEST** bit **CANCTL** register. Once in Test Mode, the **TX[1:0]**, **LBACK**, **SILENT** and **BASIC** bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The **RX** bit in the **CANTST** register allows monitoring of the **CANnRX** signal. All **CANTST** register functions are disabled when the **TEST** bit is cleared.

### 18.2.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the **SILENT** bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and it cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag,

or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

### 18.2.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the `CANnTX` signal on to the `CANnRX` signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the `LBACK` bit in the `CANTST` register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the `CANnRX` signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the `CANnTX` signal.

### 18.2.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the `CANnTX` and `CANnRX` signals. In this mode, the `CANnRX` signal is disconnected from the CAN Controller and the `CANnTX` signal is held recessive. This mode is enabled by setting both the `LBACK` and `SILENT` bits in the `CANTST` register.

### 18.2.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the `BUSY` bit of the `CANIF1CRQ` register. The CANIF1 registers are locked while the `BUSY` bit is set. The `BUSY` bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the `BUSY` bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the `BUSY` bit in the `CANIF1CRQ` register while the CANIF1 registers are locked. If the CPU has cleared the `BUSY` bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register is stored into the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the `BUSY` bit of the `CANIF2CRQ` register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the `CANIFnCMSK` registers are not evaluated. The message number of the `CANIFnCRQ` registers is also not evaluated. In the `CANIF2MCTL` register, the `NEWDAT` and `MSGLST` bits retain their function, the `DLC[3:0]` field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the `BASIC` bit in the `CANTST` register.

### 18.2.13.5 Transmit Control

Software can directly override control of the `CANnTX` signal in four different ways.

- `CANnTX` is controlled by the CAN Controller
- The sample point is driven on the `CANnTX` signal to monitor the bit timing
- `CANnTX` drives a low value

- CANnTX drives a high value

The last two functions, combined with the readable CAN receive pin CANnRX, can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the TX[1:0] field in the CANTST register. The three test functions for the CANnTX signal interfere with all CAN protocol functions. TX[1:0] must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

### 18.2.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

### 18.2.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 18-4 on page 691): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 18-1 on page 691). The length of the time quantum ( $t_q$ ), which is the basic time unit of the bit time, is defined by the CAN controller's system clock ( $f_{sys}$ ) and the Baud Rate Prescaler (BRP):

$$t_q = BRP / f_{sys}$$

The CAN module's system clock  $f_{sys}$  is the frequency of its CAN module clock input.

The Synchronization Segment  $Sync\_Seg$  is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of  $Sync\_Seg$  and the  $Sync\_Seg$  is called the *phase error* of that edge.

The Propagation Time Segment  $Prop\_Seg$  is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments  $Phase\_Seg1$  and  $Phase\_Seg2$  surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

**Figure 18-4. CAN Bit Time**

**Table 18-1. CAN Protocol Ranges<sup>a</sup>**

Parameter	Range	Remark
BRP	[1 .. 32]	Defines the length of the time quantum t <sub>q</sub>
Sync_Seg	1 t <sub>q</sub>	Fixed length, synchronization of bus input to system clock
Prop_Seg	[1 .. 8] t <sub>q</sub>	Compensates for the physical delay times
Phase_Seg1	[1 .. 8] t <sub>q</sub>	May be lengthened temporarily by synchronization
Phase_Seg2	[1 .. 8] t <sub>q</sub>	May be shortened temporarily by synchronization
SJW	[1 .. 4] t <sub>q</sub>	May not be longer than either Phase Buffer Segment

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. The sum of Prop\_Seg and Phase\_Seg1 (as TSEG1) is combined with Phase\_Seg2 (as TSEG2) in one byte, and SJW and BRP are combined in the other byte.

In these bit timing registers, the four components TSEG1, TSEG2, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits. Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (that is, the data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT).

The IPT is application-specific but may not be longer than  $2 t_q$ ; the CAN's IPT is  $0 t_q$ . Its length is the lower limit of the programmed length of `Phase_Seg2`. In case of synchronization, `Phase_Seg2` may be shortened to a value less than IPT, which does not affect bus timing.

## 18.2.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the `Prop_Seg`. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for `Prop_Seg` is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

The `Sync_Seg` is  $1 t_q$  long (fixed), which leaves  $(\text{bit time} - \text{Prop\_Seg} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, that is, `Phase_Seg2` = `Phase_Seg1`, else `Phase_Seg2` = `Phase_Seg1` + 1.

The minimum nominal length of `Phase_Seg2` has to be regarded as well. `Phase_Seg2` may not be shorter than the CAN controller's IPT, which is  $t_q$ .

The length of the synchronization jump width is set to its maximum value, which is the minimum of 4 and `Phase_Seg1`.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- `df` = Maximum tolerance of oscillator frequency
- `fosc` = Actual oscillator frequency
- `fnom` = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(\text{Phase\_Seg1}, \text{Phase\_Seg2}) \min}{2 \times (13 \times \text{tbit} - \text{Phase\_Seg2})}$$

$$df_{max} = 2 \times df \times f_{nom}$$

where:

- Phase\_Seg1 and Phase\_Seg2 are from Table 18-1 on page 691
- t<sub>bit</sub> = Bit Time
- df<sub>max</sub> = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

### 18.2.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

t<sub>q</sub> 200 ns = (BRP + 1)/CAN Clock  
 delay of bus driver 50 ns  
 delay of receiver circuit 30 ns  
 delay of bus line (40m) 220 ns  
 t<sub>Prop</sub> 400 ns = 2 × t<sub>q</sub>  
 t<sub>SJW</sub> 200 ns = 1 × t<sub>q</sub>  
 t<sub>TSeg1</sub> 600 ns = t<sub>Prop</sub> + t<sub>SJW</sub>  
 t<sub>TSeg2</sub> 200 ns = (Information Processing Time + 1) × t<sub>q</sub>  
 t<sub>Sync-Seg</sub> 200 ns = 1 × t<sub>q</sub>  
 bit time 1000 ns = t<sub>Sync-Seg</sub> + t<sub>TSeg1</sub> + t<sub>TSeg2</sub>

In the above example, the bit field values for the **CANBIT** register are: TSEG2=1, TSEG1=2, SJW=0 and BRP=3. This makes the final value programmed into the **CANBIT** register = 0x3FC0.

### 18.2.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

t<sub>q</sub> 500 ns = (BRP + 1)/CAN clock  
 delay of bus driver 200 ns  
 delay of receiver circuit 80 ns  
 delay of bus line (40m) 220 ns  
 t<sub>Prop</sub> 4.5 μs = 9 × t<sub>q</sub>  
 t<sub>SJW</sub> 2 μs = 4 × t<sub>q</sub>  
 t<sub>TSeg1</sub> 6.5 μs = t<sub>Prop</sub> + t<sub>SJW</sub>  
 t<sub>TSeg2</sub> 3 μs = (Information Processing Time + 6) × t<sub>q</sub>  
 t<sub>Sync-Seg</sub> 500 ns = 1 × t<sub>q</sub>  
 bit time 10 μs = t<sub>Sync-Seg</sub> + t<sub>TSeg1</sub> + t<sub>TSeg2</sub>

In the above example, the bit field values for the **CANBIT** register are: TSEG2=5, TSEG1=12, SJW=3 and BRP=24. This makes the final value programmed into the **CANBIT** register = 0x5CD8.

## 18.3 Register Map

Table 18-2 on page 694 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000
- CAN1: 0x4004.1000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 158).

**Table 18-2. CAN Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	CANCTL	R/W	0x0000.0001	CAN Control	696
0x004	CANSTS	R/W	0x0000.0000	CAN Status	698
0x008	CANERR	RO	0x0000.0000	CAN Error Counter	701
0x00C	CANBIT	R/W	0x0000.2301	CAN Bit Timing	702
0x010	CANINT	RO	0x0000.0000	CAN Interrupt	704
0x014	CANTST	R/W	0x0000.0000	CAN Test	705
0x018	CANBRPE	R/W	0x0000.0000	CAN Baud Rate Prescaler Extension	707
0x020	CANIF1CRQ	R/W	0x0000.0001	CAN IF1 Command Request	708
0x024	CANIF1CMSK	R/W	0x0000.0000	CAN IF1 Command Mask	709
0x028	CANIF1MSK1	R/W	0x0000.FFFF	CAN IF1 Mask 1	711
0x02C	CANIF1MSK2	R/W	0x0000.FFFF	CAN IF1 Mask 2	712

## 18.4 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

### Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing `INIT`. If the device goes bus-off, it sets `INIT`, stopping all bus activities. Once `INIT` has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 \* 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after `INIT` is cleared, each time a sequence of 11 High bits has been monitored, a `BITERROR0` code is written to the **CANSTS** register (the `LEC` field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

#### CAN Control (CANCTL)

CAN0 base: 0x4004.0000  
 CAN1 base: 0x4004.1000  
 Offset 0x000  
 Type R/W, reset 0x0000.0001

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	TEST	R/W	0	Test Mode Enable 0: Normal operation 1: Test mode
6	CCE	R/W	0	Configuration Change Enable 0: Do not allow write access to the <b>CANBIT</b> register. 1: Allow write access to the <b>CANBIT</b> register if the <code>INIT</code> bit is 1.
5	DAR	R/W	0	Disable Automatic-Retransmission 0: Auto-retransmission of disturbed messages is enabled. 1: Auto-retransmission is disabled.
4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

---

Bit/Field	Name	Type	Reset	Description
3	EIE	R/W	0	Error Interrupt Enable 0: Disabled. No error status interrupt is generated. 1: Enabled. A change in the <i>BOFF</i> or <i>EWARN</i> bits in the <b>CANSTS</b> register generates an interrupt.
2	SIE	R/W	0	Status Interrupt Enable 0: Disabled. No status interrupt is generated. 1: Enabled. An interrupt is generated when a message has successfully been transmitted or received, or a CAN bus error has been detected. A change in the <i>TXOK</i> , <i>RXOK</i> or <i>LEC</i> bits in the <b>CANSTS</b> register generates an interrupt.
1	IE	R/W	0	CAN Interrupt Enable 0: Interrupts disabled. 1: Interrupts enabled.
0	INIT	R/W	1	Initialization 0: Normal operation. 1: Initialization started.

## Register 2: CAN Status (CANSTS), offset 0x004

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

### CAN Status (CANSTS)

CAN0 base: 0x4004.0000  
 CAN1 base: 0x4004.1000  
 Offset 0x004

31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15	RP	RO	0	Received Error Passive 0: The Receive Error counter is below the Error Passive level (127 or less). 1: The Receive Error counter has reached the Error Passive level (128 or greater).
14:8	REC	RO	0x00	Receive Error Counter State of the receiver error counter (0 to 127).
7:0	TEC	RO	0x00	Transmit Error Counter State of the transmit error counter (0 to 255).

### Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the `CCE` and `INIT` bits in the `CANCTL` register. See “Bit Time and Bit Rate” on page 690 for more information.

#### CAN Bit Timing (CANBIT)

CAN0 base: 0x4004.0000  
 CAN1 base: 0x4004.1000  
 Offset 0x00C  
 Type R/W, reset 0x0000.2301

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved	TSEG2			TSEG1				SJW		BRP					
Type	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	0	0	0	1	1	0	0	0	0	0	0	0	1

Bit/Field	Name	Type	Reset	Description
31:15	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:12	TSEG2	R/W	0x2	Time Segment after Sample Point  0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.  So, for example, a reset value of 0x2 defines that there is 3 (2+1) bit time quanta defined for <code>Phase_Seg2</code> (see Figure 18-4 on page 691). The bit time quanta is defined by the <code>BRP</code> field.
11:8	TSEG1	R/W	0x3	Time Segment Before Sample Point  0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.  So, for example, the reset value of 0x3 defines that there is 4 (3+1) bit time quanta defined for <code>Phase_Seg1</code> (see Figure 18-4 on page 691). The bit time quanta is define by the <code>BRP</code> field.
7:6	SJW	R/W	0x0	(Re)Synchronization Jump Width  0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.  During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of <code>TSEG2</code> or <code>TSEG1</code> by the value in <code>SJW</code> . So the reset value of 0 adjusts the length by 1 bit time quanta.

---

Bit/Field	Name	Type	Reset	Description
5:0	BRP	R/W	0x1	<p>Baud Rate Prescaler</p> <p>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.</p> <p>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.</p> <p>BRP defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).</p> <p>The <b>CANBRPE</b> register can be used to further divide the bit time.</p>

### Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the **INTID** field is not 0x0000 (the default) and the **IE** bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the **INTID** field is cleared by reading the **CANSTS** register, or until the **IE** bit in the **CANCTL** register is cleared.

**Note:** Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

#### CAN Interrupt (CANINT)

0x8001-0xFFFF	Unused															

## Register 6: CAN Test (CANTST), offset 0x014

This is the test mode register for self-test and external pin access. It is write-enabled by setting the **TEST** bit in the **CANCTL** register. Different test functions may be combined, however, CAN transfers will be affected if the **TX** bits in this register are not zero.

### CAN Test (CANTST)

CAN0 base: 0x4004.0000  
 CAN1 base: 0x4004.1000  
 Offset 0x014  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	RX	RO	0	Receive Observation Displays the value on the $CANnRx$ pin.
6:5	TX	R/W	0x0	Transmit Control Overrides control of the $CANnTx$ pin.  Value Description 0x0 $CANnTx$ is controlled by the CAN module; default operation 0x1 The sample point is driven on the $CANnTx$ signal. This mode is useful to monitor bit timing. 0x2 $CANnTx$ drives a low value. This mode is useful for checking the physical layer of the CAN bus. 0x3 $CANnTx$ drives a high value. This mode is useful for checking the physical layer of the CAN bus.
4	LBACK	R/W	0	Loopback Mode 0: Disabled. 1: Enabled. In loopback mode, the data from the transmitter is routed into the receiver. Any data on the receive input is ignored.
3	SILENT	R/W	0	Silent Mode Do not transmit data; monitor the bus. Also known as Bus Monitor mode. 0: Disabled. 1: Enabled.

Bit/Field	Name	Type	Reset	Description
2	BASIC	R/W	0	Basic Mode 0: Disabled. 1: Use <b>CANIF1</b> registers as transmit buffer, and use <b>CANIF2</b> registers as receive buffer.
1:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 7: CAN Baud Rate Prescaler Extension (CANBRPE), offset 0x018

This register is used to further divide the bit time set with the `BRP` bit in the `CANBIT` register. It is write-enabled by setting the `CCE` bit in the `CANCTL` register.

### CAN Baud Rate Prescaler Extension (CANBRPE)

CAN0 base: 0x4004.0000  
 CAN1 base: 0x4004.1000  
 Offset 0x018

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	BRPE	R/W	0x0	Baud Rate Prescaler Extension  0x00-0x0F: Extend the <code>BRP</code> bit in the <code>CANBIT</code> register to values up to 1023. The actual interpretation by the hardware is one more than the value programmed by <code>BRPE</code> (MSBs) and <code>BRP</code> (LSBs).

**Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020**

**Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the CANIF1MCTL register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN\_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

CAN IF1 Command Request (CANIF1CRQ)

CAN0 base: 0x4004.0000  
 CAN1 base: 0x4004.1000  
 Offset 0x020

Bit/Field	Name	Type	Reset	Description								
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.								
15	BUSY	RO	0	Busy Flag 0: Cleared when read/write action has finished. 1: Set when a write occurs to the message number in this register.								
14:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.								
5:0	MNUM	R/W	0x01	Message Number Selects one of the 32 message objects in the message RAM for data transfer. The message objects are numbered from 1 to 32.  <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x00</td> <td>0 is not a valid message number; it is interpreted as 0x20, or object 32.</td> </tr> <tr> <td>0x01-0x20</td> <td>Indicates specified message object 1 to 32.</td> </tr> <tr> <td>0x21-0x3F</td> <td>Not a valid message number; values are shifted and it is interpreted as 0x01-0x1F.</td> </tr> </tbody> </table>	Value	Description	0x00	0 is not a valid message number; it is interpreted as 0x20, or object 32.	0x01-0x20	Indicates specified message object 1 to 32.	0x21-0x3F	Not a valid message number; values are shifted and it is interpreted as 0x01-0x1F.
Value	Description											
0x00	0 is not a valid message number; it is interpreted as 0x20, or object 32.											
0x01-0x20	Indicates specified message object 1 to 32.											
0x21-0x3F	Not a valid message number; values are shifted and it is interpreted as 0x01-0x1F.											

**Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024****Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

## 19 Ethernet Controller

The Stellaris<sup>®</sup> Ethernet Controller consists of a fully integrated media access controller (MAC) and network physical (PHY) interface. The Ethernet Controller conforms to *IEEE 802.3* specifications and fully supports 10BASE-T and 100BASE-TX standards.

The Stellaris<sup>®</sup> Ethernet Controller module has the following features:

- Conforms to the *IEEE 802.3-2002 specification*
  - 10BASE-T/100BASE-TX IEEE-802.3 compliant. Requires only a dual 1:1 isolation transformer interface to the line
  - 10BASE-T/100BASE-TX ENDEC, 100BASE-TX scrambler/descrambler
  - Full-featured auto-negotiation
- Multiple operational modes
  - Full- and half-duplex 100 Mbps
  - Full- and half-duplex 10 Mbps
  - Power-saving and power-down modes
- Highly configurable
  - Programmable MAC address
  - LED activity selection
  - Promiscuous mode support
  - CRC error-rejection control
  - User-configurable interrupts
- Physical media manipulation
  - MDI/MDI-X cross-over support through software assist
  - Register-programmable transmit amplitude
  - Automatic polarity correction and 10BASE-T signal reception
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive channel request asserted on packet receipt
  - Transmit channel request asserted on empty transmit FIFO

## 19.1 Block Diagram

As shown in Figure 19-1 on page 724, the Ethernet Controller is functionally divided into two layers: the Media Access Controller (MAC) layer and the Network Physical (PHY) layer. These layers correspond to the OSI model layers 2 and 1. The CPU accesses the Ethernet Controller via the MAC layer. The MAC layer provides transmit and receive processing for Ethernet frames. The MAC layer also provides the interface to the PHY layer via an internal Media Independent Interface (MII). The PHY layer communicates with the Ethernet bus.

Figure 19-1. Ethernet Controller

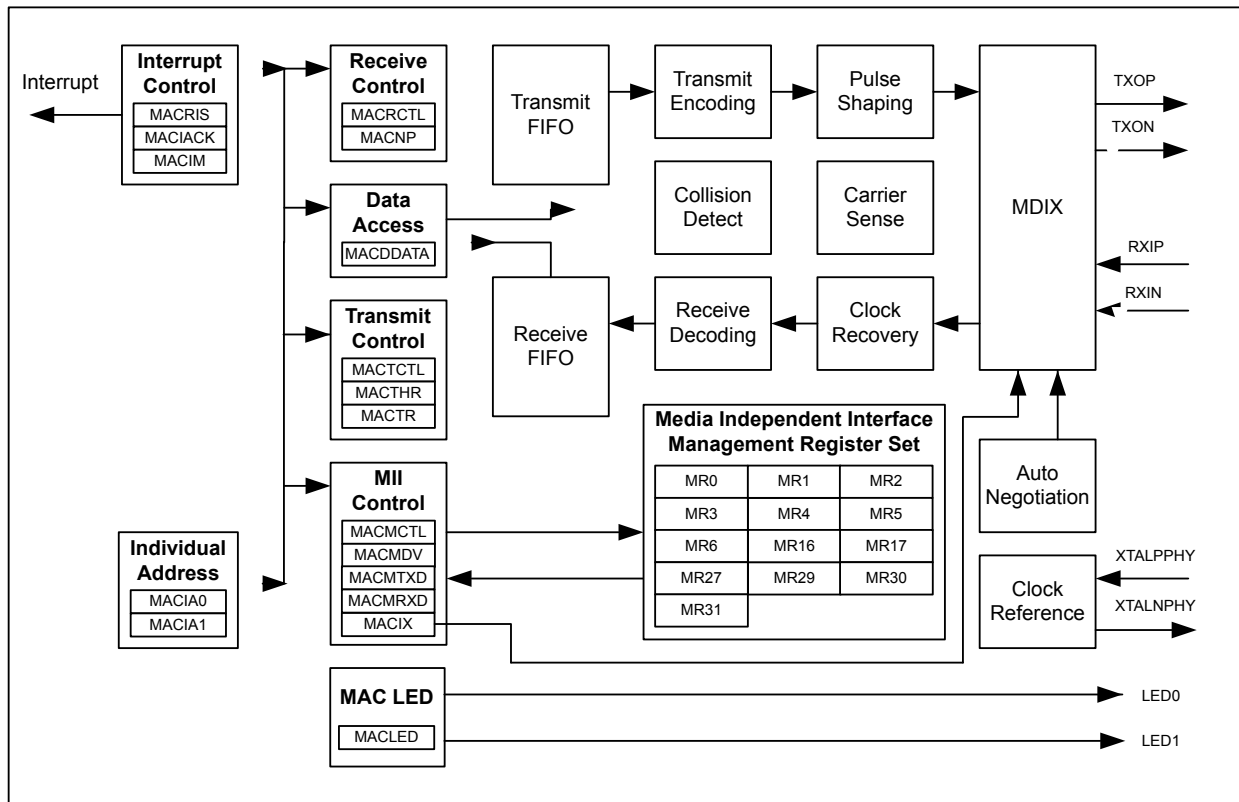

Figure 19-2 on page 724 shows more detail of the internal structure of the Ethernet Controller and how the register set relates to various functions.

Figure 19-2. Ethernet Controller Block Diagram

## 19.2 Functional Description

**Note:** A 12.4-k $\Omega$  resistor should be connected between the `ERBIAS` and ground. The 12.4-k $\Omega$  resistor should have a 1% tolerance and should be located in close proximity to the `ERBIAS` pin. Power dissipation in the resistor is low, so a chip resistor of any geometry may be used.

The functional description of the Ethernet Controller is discussed in the following sections.

### 19.2.1 MAC Operation

The following sections describe the operation of the MAC unit, including an overview of the Ethernet frame format, the MAC layer FIFOs, Ethernet transmission and reception options, and LED indicators.

#### 19.2.1.1 Ethernet Frame Format

Ethernet data is carried by Ethernet frames. The basic frame format is shown in Figure 19-3 on page 725.

**Figure 19-3. Ethernet Frame**

Preamble	SFD	Destination Address	Source Address	Length/ Type	Data	FCS
7 Bytes	1 Byte	6 Bytes	6 Bytes	2 Bytes	46 - 1500 Bytes	4 Bytes

The seven fields of the frame are transmitted from left to right. The bits within the frame are transmitted from least to most significant bit.

- **Preamble**  
The Preamble field is used to synchronize with the received frame's timing. The preamble is 7 octets long.
- **Start Frame Delimiter (SFD)**  
The SFD field follows the preamble pattern and indicates the start of the frame. Its value is 1010.1011.
- **Destination Address (DA)**  
This field specifies destination addresses for which the frame is intended. The LSB (bit 16 of DA oct 1 in the frame, see Table 19-1 on page 727) of the DA determines whether the address is an individual (0), or group/multicast (1) address.
- **Source Address (SA)**  
The source address field identifies the station from which the frame was initiated.
- **Length/Type Field**  
The meaning of this field depends on its numeric value. This field can be interpreted as length or type code. The maximum length of the data field is 1500 octets. If the value of the Length/Type field is less than or equal to 1500 decimal, it indicates the number of MAC client data octets. If the value of this field is greater than or equal to 1536 decimal, then it is type interpretation. The meaning of the Length/Type field when the value is between 1500 and 1536 decimal is unspecified by the IEEE 802.3 standard. However, the Ethernet Controller assumes type interpretation if the

value of the Length/Type field is greater than 1500 decimal. The definition of the Type field is specified in the IEEE 802.3 standard. The first of the two octets in this field is most significant.

- Data

The data field is a sequence of octets that is at least 46 in length, up to 1500 in length. Full data transparency is provided so any values can appear in this field. A minimum frame size of 46 octets is required to meet the IEEE standard. If the frame size is too small, the Ethernet Controller automatically appends extra bits (a pad), thus the pad can have a size of 0 to 46 octets. Data padding can be disabled by clearing the `PADEN` bit in the **Ethernet MAC Transmit Control (MACTCTL)** register.

For the Ethernet Controller, data sent/received can be larger than 1500 bytes without causing a Frame Too Long error. Instead, a FIFO overrun error is reported using the `FOV` bit in the **Ethernet MAC Raw Interrupt Status(MACRIS)** register when the frame received is too large to fit into the Ethernet Controller's 2K RAM.

- Frame Check Sequence (FCS)

The frame check sequence carries the cyclic redundancy check (CRC) value. The CRC is computed over the destination address, source address, length/type, and data (including pad) fields using the CRC-32 algorithm. The Ethernet Controller computes the FCS value one nibble at a time. For transmitted frames, this field is automatically inserted by the MAC layer, unless disabled by clearing the `CRC` bit in the **MACTCTL** register. For received frames, this field is automatically checked. If the FCS does not pass, the frame is not placed in the RX FIFO, unless the FCS check is disabled by clearing the `BADCRC` bit in the **MACRCTL** register.

### 19.2.1.2 MAC Layer FIFOs

The Ethernet Controller is capable of simultaneous transmission and reception. This feature is enabled by setting the `DUPLX` bit in the **MACTCTL** register.

For Ethernet frame transmission, a 2 KB transmit FIFO is provided that can be used to store a single frame. While the *IEEE 802.3 specification* limits the size of an Ethernet frame's payload section to 1500 Bytes, the Ethernet Controller places no such limit. The full buffer can be used, for a payload of up to 2032 bytes (as the first 16 bytes in the FIFO are reserved for destination address, source address and length/type information).

For Ethernet frame reception, a 2-KB receive FIFO is provided that can be used to store multiple frames, up to a maximum of 31 frames. If a frame is received, and there is insufficient space in the RX FIFO, an overflow error is indicated using the `FOV` bit in the **MACRIS** register.

For details regarding the TX and RX FIFO layout, refer to Table 19-1 on page 727. Please note the following difference between TX and RX FIFO layout. For the TX FIFO, the Data Length field in the first FIFO word refers to the Ethernet frame data payload, as shown in the 5th to nth FIFO positions. For the RX FIFO, the Frame Length field is the total length of the received Ethernet frame, including the Length/Type bytes and the FCS bits.

If FCS generation is disabled by clearing the `CRC` bit in the **MACTCTL** register, the last word in the TX FIFO must contain the FCS bytes for the frame that has been written to the FIFO.

Also note that if the length of the data payload section is not a multiple of 4, the FCS field is not be aligned on a word boundary in the FIFO. However, for the RX FIFO the beginning of the next frame is always on a word boundary.

Table 19-1. TX &amp; RX FIFO Organization

FIFO Word Read/Write Sequence	Word Bit Fields	TX FIFO (Write)	RX FIFO (Read)
1st	7:0	Data Length Least Significant Byte	Frame Length Least Significant Byte
	15:8	Data Length Most Significant Byte	Frame Length Most Significant Byte
	23:16		DA oct 1
	31:24		DA oct 2
2nd	7:0		DA oct 3
	15:8		DA oct 4
	23:16		DA oct 5
	31:24		DA oct 6
3rd	7:0		SA oct 1
	15:8		SA oct 2
	23:16		SA oct 3
	31:24		SA oct 4
4th	7:0		SA oct 5
	15:8		SA oct 6
	23:16		Len/Type Most Significant Byte
	31:24		Len/Type Least Significant Byte
5th to nth	7:0		data oct n
	15:8		data oct n+1
	23:16		data oct n+2
	31:24		data oct n+3
last	7:0		FCS 1
	15:8		FCS 2
	23:16		FCS 3
	31:24		FCS 4

**Note:** If the CRC bit in the **MACTCTL** register is clear, the FCS bytes must be written with the correct CRC. If the CRC bit is set, the Ethernet Controller automatically writes the FCS bytes.

### 19.2.1.3 Ethernet Transmission Options

At the MAC layer, the transmitter can be configured for both full-duplex and half-duplex operation by using the **DUPLEX** bit in the **MACTCTL** register.

The Ethernet Controller automatically generates and inserts the Frame Check Sequence (FCS) at the end of the transmit frame when the CRC bit in the **MACTCTL** register is set. However, for test purposes, this feature can be disabled in order to generate a frame with an invalid CRC by clearing the CRC bit.

The *IEEE 802.3 specification* requires that the Ethernet frame payload section be a minimum of 46 bytes. The Ethernet Controller automatically pads the data section if the payload data section loaded into the FIFO is less than the minimum 46 bytes when the **PADEN** bit in the **MACTCTL** register is set. This feature can be disabled by clearing the **PADEN** bit.

The transmitter must be enabled by setting the **TXEN** bit in the **TCTL** register.

#### 19.2.1.4 Ethernet Reception Options

The Ethernet Controller RX FIFO should be cleared during software initialization. The receiver should first be disabled by clearing the `RXEN` bit in the **Ethernet MAC Receive Control (MACRCTL)** register, then the FIFO can be cleared by setting the `RSTFIFO` bit in the **MACRCTL** register.

The receiver automatically rejects frames that contain bad CRC values in the FCS field. In this case, a Receive Error interrupt is generated and the receive data is lost. To accept all frames, clear the `BADCRC` bit in the **MACRCTL** register.

In normal operating mode, the receiver accepts only those frames that have a destination address that matches the address programmed into the **Ethernet MAC Individual Address 0 (MACIA0)** and **Ethernet MAC Individual Address 1 (MACIA1)** registers. However, the Ethernet receiver can also be configured for Promiscuous and Multicast modes by setting the `PRMS` and `AMUL` bits in the **MACRCTL** register.

#### 19.2.1.5 LED Indicators

The Ethernet Controller supports two LED signals that can be used to indicate various states of operation. These signals are mapped to the `LED0` and `LED1` pins. By default, these pins are configured as GPIO signals (`PF3` and `PF2`). For the Ethernet Controller to drive these signals, they must be reconfigured to their hardware function. See “General-Purpose Input/Outputs (GPIOs)” on page 291 for additional details. The function of these pins is programmable using the **Ethernet MAC LED Encoding (MACLED)** register. Refer to page 752 for additional details on how to program these LED functions.

#### 19.2.2 Internal MII Operation

For the MII management interface to function properly, the `MDIO` signal must be connected through a 10k  $\Omega$  pull-up resistor to the +3.3 V supply. Failure to connect this pull-up resistor prevents management transactions on this internal MII to function. Note that it is possible for data transmission across the MII to still function since the PHY layer auto-negotiates the link parameters by default.

For the MII management interface to function properly, the internal clock must be divided down from the system clock to a frequency no greater than 2.5 MHz. The **Ethernet MAC Management Divider (MACMDV)** register contains the divider used for scaling down the system clock. See page 747 for more details about the use of this register.

#### 19.2.3 PHY Operation

The Physical Layer (PHY) in the Ethernet Controller includes integrated ENDECs, scrambler/descrambler, dual-speed clock recovery, and full-featured auto-negotiation functions. The transmitter includes an on-chip pulse shaper and a low-power line driver. The receiver has an adaptive equalizer and a baseline restoration circuit required for accurate clock and data recovery. The transceiver interfaces to Category-5 unshielded twisted pair (Cat-5 UTP) cabling for 100BASE-TX applications, and Category-3 unshielded twisted pair (Cat-3 UTP) for 10BASE-T applications. The Ethernet Controller is connected to the line media via dual 1:1 isolation transformers. No external filter is required.

##### 19.2.3.1 Clock Selection

The Ethernet Controller has an on-chip crystal oscillator which can also be driven by an external oscillator. In this mode of operation, a 25-MHz crystal should be connected between the `XTALPPHY` and `XTALNPHY` pins. Alternatively, an external 25-MHz clock input can be connected to the `XTALPPHY` pin. In this mode of operation, a crystal is not required and the `XTALNPHY` pin must be tied to ground.

See “Ethernet Controller” on page 1016 for more information regarding the specifications of the Ethernet Controller.

### 19.2.3.2 Auto-Negotiation

The Ethernet Controller supports the auto-negotiation functions of Clause 28 of the *IEEE 802.3* standard for 10/100 Mbps operation over copper wiring. This function is controlled via register settings. The auto-negotiation function is turned on by default, and the `ANEGEN` bit in the **Ethernet PHY Management Register 0 - Control (MR0)** is set after reset. Software can disable the auto-negotiation function by clearing the `ANEGEN` bit. The contents of the **Ethernet PHY Management Register - Auto-Negotiation Advertisement (MR4)** are reflected to the Ethernet Controller’s link partner during auto-negotiation via fast-link pulse coding.

Once auto-negotiation is complete, the `SPEED` bit in the **Ethernet PHY Management Register 31 – PHY Special Control/Status (MR31)** register reflects the actual speed. The `AUTODONE` bit in **MR31** is set to indicate that auto-negotiation is complete. Setting the `RANEG` bit in the **MR0** register also causes auto-negotiation to restart.

### 19.2.3.3 Polarity Correction

The Ethernet Controller is capable of automatic polarity reversal for 10BASE-T and auto-negotiation functions. The `XPOL` bit in the **Ethernet PHY Management Register 27 –Special Control/Status (MR27)** register is set to indicate the polarity has automatically been reversed.

### 19.2.3.4 MDI/MDI-X Configuration

The Ethernet Controller supports the MDI/MDI-X configuration as defined in *IEEE 802.3-2002 specification* through software assistance. The MDI/MDI-X configuration eliminates the need for cross-over cables when connecting to another device, such as a hub. Software can implement the MDI/MDI-X configuration by using any available timer resource such as SysTick (see “System Timer (SysTick)” on page 69 for more information) to implement this functionality. Once the Ethernet Controller has been configured and enabled, software should check to see if the `LINK` bit in the **Ethernet PHY Management Register 1 - Status (MR1)** has been set within approximately 60 ms; if not, set the `EN` bit of the **Ethernet PHY MDIX (MDIX)** register to switch the reverse the transmit and receive lines to the PHY layer.

## 19.2.4 Interrupts

The Ethernet Controller can generate an interrupt for one or more of the following conditions:

- A frame has been received into an empty RX FIFO
- A frame transmission error has occurred
- A frame has been transmitted successfully
- A frame has been received with inadequate room in the RX FIFO (overrun)
- A frame has been received with one or more error conditions (for example, FCS failed)
- An MII management transaction between the MAC and PHY layers has completed
- One or more of the following PHY layer conditions occurs:
  - Auto-Negotiate Complete

- Remote Fault
- Link Partner Acknowledge
- Parallel Detect Fault
- Page Received

Refer to **Ethernet PHY Management Register 29 - Interrupt Source Flags (MR29)** (see page 768) for additional details regarding PHY interrupts.

### 19.2.5 DMA Operation

The Ethernet peripheral provides request signals to the  $\mu$ DMA controller, one for transmit and one for receive. There is a dedicated  $\mu$ DMA channel for each. The request is a single type for both channels. Burst requests are not supported. The RX channel request is asserted when a packet is received while the TX channel request is asserted when the transmit FIFO becomes empty.

No special configuration is needed to enable the Ethernet peripheral for use with the  $\mu$ DMA controller.

Because the size of a received packet is not known until the header is examined, it is best to set up the initial  $\mu$ DMA transfer to copy the first 4 words from the RX FIFO when the RX request occurs. This will include the packet length plus the Ethernet header. The  $\mu$ DMA will then cause an interrupt when this transfer is complete. Upon entering the interrupt handler, the packet length in the FIFO and the Ethernet header will be in a buffer and can be examined. Once the packet length is known then another  $\mu$ DMA transfer can be set up to transfer the remaining received packet payload from the FIFO into a buffer. This transfer should be initiated by software. Another interrupt will occur when this transfer is done.

Even though the TX channel will generate a TX empty request, the recommended way to handle  $\mu$ DMA transfers for transmitting packets is to set up the transfer from the buffer containing the packet to the transmit FIFO, and then to initiate the transfer with a software request. An interrupt will occur when this transfer is complete. For both channels, the "auto-request" transfer mode should be used. See "Micro Direct Memory Access ( $\mu$ DMA)" on page 226 for more details about programming the  $\mu$ DMA controller.

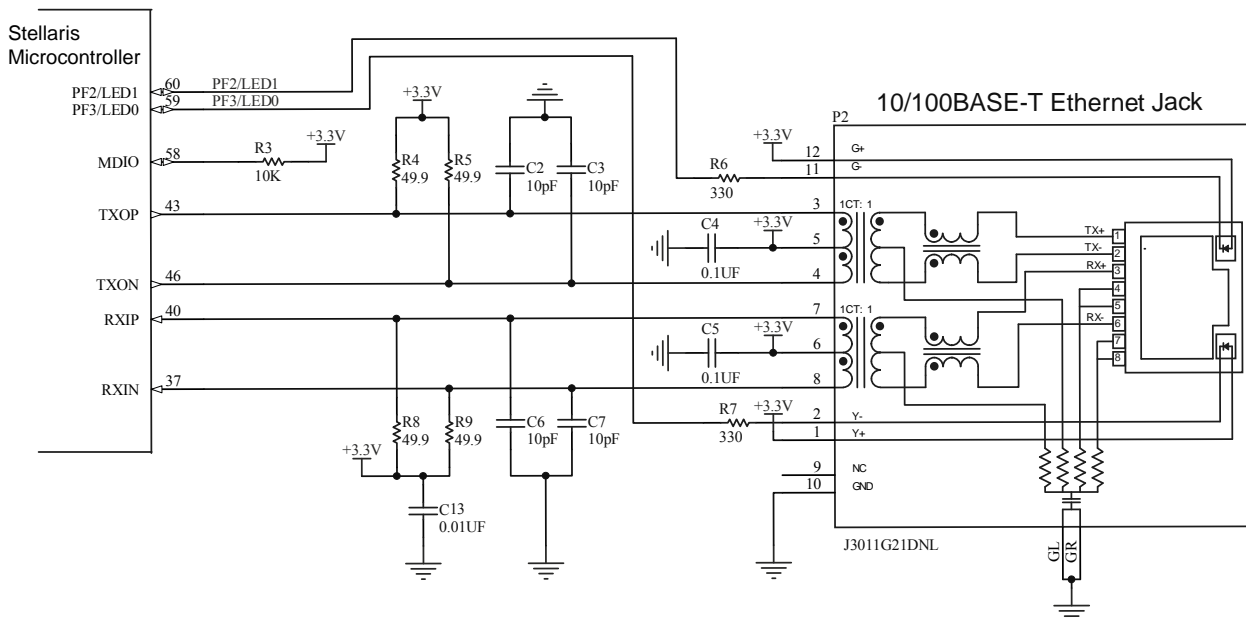

## 19.3 Initialization and Configuration

The following sections describe the hardware and software configuration required to set up the Ethernet Controller.

### 19.3.1 Hardware Configuration

Figure 19-4 on page 731 shows the proper method for interfacing the Ethernet Controller to a 10/100BASE-T Ethernet jack.

Figure 19-4. Interface to an Ethernet Jack

The following isolation transformers have been tested and are known to successfully interface to the Ethernet PHY layer.

- Isolation Transformers
  - TDK TLA-6T103
  - Bel-Fuse S558-5999-46
  - Halo TG22-3506ND
  - Pulse PE-68515
  - Valor ST6118
  - YCL 20PMT04
- Isolation transformers in low profile packages (0.100 in/2.5 mm or less)
  - TDK TLA-6T118
  - Halo TG110-S050
  - PCA EPF8023G
- Isolation transformers with integrated RJ45 connector
  - TDK TLA-6T704
  - Delta RJS-1A08T089A
- Isolation transformers with integrated RJ45 connector, LEDs and termination resistors
  - Pulse J0011D21B/E
  - Pulse J3011G21DNL

### 19.3.2 Software Configuration

To use the Ethernet Controller, it must be enabled by setting the `EPHY0` and `EMAC0` bits in the `RCGC2` register (see page 179). In addition, the clock to the appropriate GPIO module must be enabled via the `RCGC2` register in the System Control module. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.

The following steps can then be used to configure the Ethernet Controller for basic operation.

1. Program the `MACDIV` register to obtain a 2.5 MHz clock (or less) on the internal MII. Assuming a 20-MHz system clock, the `MACDIV` value should be 0x03 or greater.

2. Program the **MACIA0** and **MACIA1** register for address filtering.
3. Program the **MACTCTL** register for Auto CRC generation, padding, and full-duplex operation using a value of 0x16.
4. Program the **MACRCTL** register to flush the receive FIFO and reject frames with bad FCS using a value of 0x18.
5. Enable both the Transmitter and Receive by setting the LSB in both the **MACTCTL** and **MACRCTL** registers.
6. To transmit a frame, write the frame into the TX FIFO using the **Ethernet MAC Data (MACDATA)** register. Then set the **NEWTX** bit in the **Ethernet Mac Transmission Request (MACTR)** register to initiate the transmit process. When the **NEWTX** bit has been cleared, the TX FIFO is available for the next transmit frame.
7. To receive a frame, wait for the **NPR** field in the **Ethernet MAC Number of Packets (MACNP)** register to be non-zero. Then begin reading the frame from the RX FIFO by using the **MACDATA** register. When the frame (including the FCS field) has been read, the **NPR** field decrements by one. When there are no more frames in the RX FIFO, the **NPR** field reads 0.

## 19.4 Ethernet Register Map

Table 19-2 on page 732 lists the Ethernet MAC registers. All addresses given are relative to the Ethernet MAC base address of 0x4004.8000. Note that the Ethernet controller clocks must be enabled before the registers can be programmed (see page 179).

The *IEEE 802.3* standard specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers and are detailed in Section 22.2.4 of the *IEEE 802.3 specification*. Table 19-2 on page 732 also lists these MII Management registers. *All addresses given are absolute and are written directly to the REGADR field of the Ethernet MAC Management Control (MACMCTL) register.* The format of registers 0 to 15 are defined by the IEEE specification and are common to all PHY layer implementations. The only variance allowed is for features that may or may not be supported by a specific PHY implementation. Registers 16 to 31 are vendor-specific registers, used to support features that are specific to a vendor's PHY implementation. Vendor-specific registers not listed are reserved.

**Table 19-2. Ethernet Register Map**

## 19.5 Ethernet MAC Register Descriptions

The remainder of this section lists and describes the Ethernet MAC registers, in numerical order by address offset. Also see “MII Management Register Descriptions” on page 753.

## Register 1: Ethernet MAC Raw Interrupt Status/Acknowledge (MACRIS/MACIACK), offset 0x000

The **MACRIS/MACIACK** register is the interrupt status and acknowledge register. On a read, this register gives the current status value of the corresponding interrupt prior to masking. On a write, setting any bit clears the corresponding interrupt status bit.

### Reads

#### Ethernet MAC Raw Interrupt Status/Acknowledge (MACRIS/MACIACK)

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PHYINT	RO	0	PHY Interrupt  When set, indicates that an enabled interrupt in the PHY layer has occurred. <b>MR29</b> in the PHY must be read to determine the specific PHY event that triggered this interrupt.
5	MDINT	RO	0	MII Transaction Complete  When set, indicates that a transaction (read or write) on the MII interface has completed successfully.
4	RXER	RO	0	Receive Error  This bit indicates that an error was encountered on the receiver. The possible errors that can cause this interrupt bit to be set are: <ul style="list-style-type: none"> <li>■ A receive error occurs during the reception of a frame (100 Mb/s only).</li> <li>■ The frame is not an integer number of bytes (dribble bits) due to an alignment error.</li> <li>■ The CRC of the frame does not pass the FCS check.</li> <li>■ The length/type field is inconsistent with the frame data size when interpreted as a length field.</li> </ul>
3	FOV	RO	0	FIFO Overrun  When set, indicates that an overrun was encountered on the receive FIFO.

Bit/Field	Name	Type	Reset	Description
2	TXEMP	RO	0	Transmit FIFO Empty When set, indicates that the packet was transmitted and that the TX FIFO is empty.
1	TXER	RO	0	Transmit Error When set, indicates that an error was encountered on the transmitter. The possible errors that can cause this interrupt bit to be set are: <ul style="list-style-type: none"> <li>The data length field stored in the TX FIFO exceeds 2032 decimal (buffer length - 16 bytes of header data). The frame is not sent when this error occurs.</li> <li>The retransmission attempts during the backoff process have exceeded the maximum limit of 16 decimal.</li> </ul>
0	RXINT	RO	0	Packet Received When set, indicates that at least one packet has been received and is stored in the receiver FIFO.

3	FOVM	R/W	1	Mask FIFO Overrun  Clearing this bit masks the <code>FOV</code> bit in the <b>MACRIS</b> register from being set.
2	TXEMPM	R/W	1	Mask Transmit FIFO Empty  Clearing this bit masks the <code>TXEMP</code> bit in the <b>MACRIS</b> register from being set.
1	TXERM	R/W	1	Mask Transmit Error  Clearing this bit masks the <code>TXER</code> bit in the <b>MACRIS</b> register from being set.
0	RXINTM	R/W	1	Mask Packet Received  Clearing this bit masks the <code>RXINT</code> bit in the <b>MACRIS</b> register from being set.

### Register 3: Ethernet MAC Receive Control (MACRCTL), offset 0x008

This register configures the receiver and controls the types of frames that are received.

It is important to note that when the receiver is enabled, all valid frames with a broadcast address of FF-FF-FF-FF-FF-FF in the Destination Address field are received and stored in the RX FIFO, even if the `AMUL` bit is not set.

#### Ethernet MAC Receive Control (MACRCTL)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	DUPLEX	R/W	0	Enable Duplex Mode  When set, this bit enables Duplex mode, allowing simultaneous transmission and reception.
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	CRC	R/W	0	Enable CRC Generation  When set this bit enables the automatic generation of the CRC and its placement at the end of the packet. If this bit is clear, the frames placed in the TX FIFO are sent exactly as they are written into the FIFO.  Note that this bit should generally be set.
1	PADEN	R/W	0	Enable Packet Padding  When set, this bit enables the automatic padding of packets that do not meet the minimum frame size.  Note that this bit should generally be set.
0	TXEN	R/W	0	Enable Transmitter  When set, this bit enables the transmitter. When this bit is clear, the transmitter is disabled.

### Register 5: Ethernet MAC Data (MACDATA), offset 0x010

This register enables software to access the TX and RX FIFOs.

Reads from this register return the data stored in the RX FIFO from the location indicated by the read pointer. The read pointer is then auto incremented to the next RX FIFO location. Reading from the RX FIFO when a frame has not been received or is in the process of being received will return indeterminate data and not increment the read pointer.

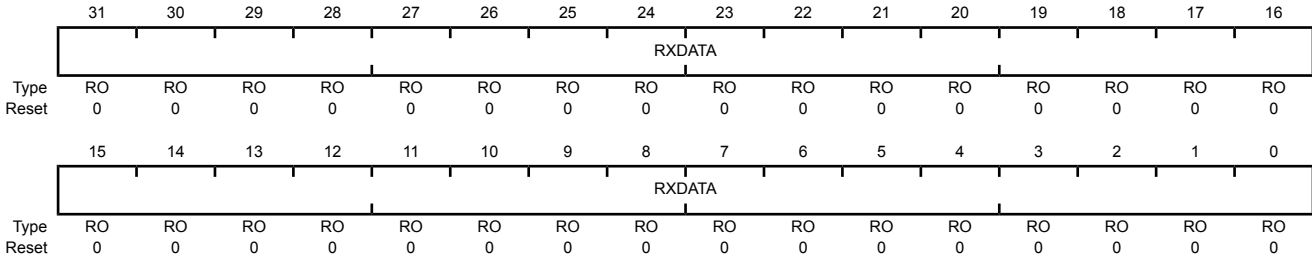

Writes to this register store the data in the TX FIFO at the location indicated by the write pointer. The write pointer is the auto incremented to the next TX FIFO location. Writing more data into the TX FIFO than indicated in the length field will result in the data being lost. Writing less data into the TX FIFO than indicated in the length field will result in indeterminate data being appended to the end of the frame to achieve the indicated length. Attempting to write the next frame into the TX FIFO before transmission of the first has completed will result in the data being lost.

There is no mechanism for randomly accessing bytes in either the RX or TX FIFOs. Data must be read from the RX FIFO sequentially and stored in a buffer for further processing. Once a read has been performed, the data in the FIFO cannot be re-read. Data must be written to the TX FIFO sequentially. If an error is made in placing the frame into the TX FIFO, the write pointer can be reset to the start of the TX FIFO by writing the `TXER` bit of the `MACIACK` register and then the data re-written.

#### Reads

##### Ethernet MAC Data (MACDATA)

Bit/Field	Name	Type	Reset	Description
31:0	TXDATA	WO	0x0000.0000	Transmit FIFO Data

The TXDATA bits represent the next word of data to place in the TX FIFO for transmission.

## Register 6: Ethernet MAC Individual Address 0 (MACIA0), offset 0x014

This register enables software to program the first four bytes of the hardware MAC address of the Network Interface Card (NIC). (The last two bytes are in **MACIA1**). The 6-byte Individual Address is compared against the incoming Destination Address fields to determine whether the frame should be received.

### Ethernet MAC Individual Address 0 (MACIA0)

7:0	MACOCT5	R/W	0x00	MAC Address Octet 5  The <b>MACOCT5</b> bits represent the fifth octet of the MAC address used to uniquely identify the Ethernet Controller.

### Register 8: Ethernet MAC Threshold (MACTHR), offset 0x01C

In order to increase the transmission rate, it is possible to program the Ethernet Controller to begin transmission of the next frame prior to the completion of the transmission of the current frame. Note: Extreme care must be used when implementing this function. Software must be able to guarantee that the complete frame is able to be stored in the transmission FIFO prior to the completion of the transmission frame.

This register enables software to set the threshold level at which the transmission of the frame begins. If the THRESH bits are set to 0x3F, which is the reset value, the early transmission feature is disabled, and transmission does not start until the NEWTX bit is set in the MACTR register.

Writing the THRESH bits to any value besides 0x3F enables the early transmission feature. Once the byte count of data in the TX FIFO reaches the value derived from the THRESH bits as shown below, transmission of the frame begins. When THRESH is set to all 0s, transmission of the frame begins after 4 bytes (a single write) are stored in the TX FIFO. Each increment of the THRESH bit field waits for an additional 32 bytes of data (eight writes) to be stored in the TX FIFO. Therefore, a value of 0x01 causes the transmitter to wait for 36 bytes of data to be written while a value of 0x02 makes the wait equal to 68 bytes of written data. In general, early transmission starts when:

$$\text{Number of Bytes} \geq 4 (\text{THRESH} \times 8 + 1)$$

Reaching the threshold level has the same effect as setting the NEWTX bit in the MACTR register. Transmission of the frame begins and then the number of bytes indicated by the Data Length field is transmitted. Because under-run checking is not performed, if any event, such as an interrupt, delays the filling of the FIFO, the tail pointer may reach and pass the write pointer in the TX FIFO. In this event, indeterminate values are transmitted rather than the end of the frame. Therefore, sufficient bus bandwidth for writing to the TX FIFO must be guaranteed by the software.

If a frame smaller than the threshold level must be sent, the NEWTX bit in the MACTR register must be set with an explicit write. This initiates the transmission of the frame even though the threshold limit has not been reached.

If the threshold level is set too small, it is possible for the transmitter to underrun. If this occurs, the transmit frame is aborted, and a transmit error occurs. Note that in this case, the TXER bit in the MACRIS is not set meaning that the CPU receives no indication that a transmit error happened.

#### Ethernet MAC Threshold (MACTHR)

Base 0x4004.8000  
 Offset 0x01C  
 Type R/W, reset 0x0000.003F

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
5:0	THRESH	R/W	0x3F	Threshold Value  The THRESH bits represent the early transmit threshold. Once the amount of data in the TX FIFO exceeds the value represented by the above equation, transmission of the packet begins.

## Register 9: Ethernet MAC Management Control (MACMCTL), offset 0x020

This register enables software to control the transfer of data to and from the MII Management registers in the Ethernet PHY layer. The address, name, type, reset configuration, and functional description of each of these registers can be found in Table 19-2 on page 732 and in “MII Management Register Descriptions” on page 753.

In order to initiate a *read* transaction from the MII Management registers, the `WRITE` bit must be cleared during the same cycle that the `START` bit is set.

In order to initiate a *write* transaction to the MII Management registers, the `WRITE` bit must be set during the same cycle that the `START` bit is set.

### Ethernet MAC Management Control (MACMCTL)

Base 0x4004.8000  
Offset 0x020  
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:3	REGADR	R/W	0x0	MII Register Address  The <code>REGADR</code> bit field represents the MII Management register address for the next MII management interface transaction. Refer to Table 19-2 on page 732 for the PHY register offsets.  Note that any address that is not valid in the register map should not be written to and any data read should be ignored.
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	WRITE	R/W	0	MII Register Transaction Type  The <code>WRITE</code> bit represents the operation of the next MII management interface transaction. If <code>WRITE</code> is set, the next operation is a write; if <code>WRITE</code> is clear, the next transaction is a read.
0	START	R/W	0	MII Register Transaction Enable  The <code>START</code> bit represents the initiation of the next MII management interface transaction. When this bit is set, the MII register located at <code>REGADR</code> is read ( <code>WRITE=0</code> ) or written ( <code>WRITE=1</code> ).

## Register 10: Ethernet MAC Management Divider (MACMDV), offset 0x024

This register enables software to set the clock divider for the Management Data Clock (MDC). This clock is used to synchronize read and write transactions between the system and the MII Management registers. The frequency of the MDC clock can be calculated from the following formula:

$$F_{mdc} = \frac{F_{ipclk}}{2 \times (MACDVR + 1)}$$

The clock divider must be written with a value that ensures that the MDC clock does not exceed a frequency of 2.5 MHz.

### Ethernet MAC Management Divider (MACMDV)

## Register 16: Ethernet PHY MDIX (MDIX), offset 0x044

This register enables the transmit and receive lines to be reversed in order to implement the MDI/MDI-X functionality. Software can implement the MDI/MDI-X configuration by using any available timer resource such as SysTick (see “System Timer (SysTick)” on page 69 for more information) to implement this functionality. Once the Ethernet Controller has been configured and enabled, software should check to see if the `LINK` bit in the **MR1** register has been set within approximately 60 ms; if not, set the `EN` bit of the **MDIX** register to switch the reverse the transmit and receive lines to the PHY layer. Software should check the `LINK` bit again after approximately another 60 ms and if no link has been established, the `EN` bit should be cleared. Software must continue to change the termination back and forth by setting and clearing the `EN` bit every 60 msec until a link is established.

### Ethernet PHY MDIX (MDIX)

0	EN	R/W	0	MDI/MDI-X Enable  When set, the transmit and receive signals are switched such that data is received on the transmit signals <code>TXOP</code> and <code>TXON</code> ; data is transmitted on the receive signals <code>RXIP</code> and <code>RXIN</code> .

## 19.6 MII Management Register Descriptions

The *IEEE 802.3 standard* specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers. All addresses given are absolute. Addresses not listed are reserved; these addresses should not be written to and any data read should be ignored. Also see “Ethernet MAC Register Descriptions” on page 733.

## Register 17: Ethernet PHY Management Register 0 – Control (MR0), address 0x00

This register enables software to configure the operation of the PHY layer. The default settings of these registers are designed to initialize the Ethernet Controller to a normal operational mode without configuration.

### Ethernet PHY Management Register 0 – Control (MR0)

Base 0x4004.8000

Address 0x00

Type R/W, reset 0x3100

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RESET	LOOPBK	SPEEDSL	ANEGEN	PWRDN	ISO	RANEG	DUPLEX	COLT	reserved						
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	1	0	0	0	1	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
15	RESET	R/W	0	Reset Registers  When set, this bit resets the PHY layer registers to their default state and reinitializes internal state machines. Once the reset operation has completed, this bit is cleared by hardware.
14	LOOPBK	R/W	0	Loopback Mode  When set, this bit enables the Loopback mode of operation. The receiver ignores external inputs and receives the data that is transmitted by the transmitter.
13	SPEEDSL	R/W	1	Speed Select  Value Description 1 Enables the 100 Mb/s mode of operation (100BASE-TX). 0 Enables the 10 Mb/s mode of operation (10BASE-T).
12	ANEGEN	R/W	1	Auto-Negotiation Enable  When set, this bit enables the auto-negotiation process.
11	PWRDN	R/W	0	Power Down  When set, this bit places the PHY layer into a low-power consuming state. All data on the data inputs is ignored.
10	ISO	R/W	0	Isolate  When set, this bit isolates the transmit and receive data paths and ignores all data being transmitted and received.
9	RANEG	R/W	0	Restart Auto-Negotiation  When set, this bit restarts the auto-negotiation process. Once the restart has initiated, this bit is cleared by hardware.

Bit/Field	Name	Type	Reset	Description
8	DUPLEX	R/W	1	Set Duplex Mode  Value Description 1 Enables the Full-Duplex mode of operation. This bit can be set by software in a manual configuration process or by the auto-negotiation process. 0 Enables the Half-Duplex mode of operation.
7	COLT	R/W	0	Collision Test  When set, this bit enables the Collision Test mode of operation. The COLT bit is set after the initiation of a transmission and is cleared once the transmission is halted.
6:0	reserved	R/W	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  These bits should always be written as zero.

## Register 18: Ethernet PHY Management Register 1 – Status (MR1), address 0x01

This register enables software to determine the capabilities of the PHY layer and perform its initialization and operation appropriately.

### Ethernet PHY Management Register 1 – Status (MR1)

Base 0x4004.8000

Address 0x01

Type RO, reset 0x7849

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	1	1	1	1	0	0	0	0	0	0	0	1	0	0	1

Bit/Field	Name	Type	Reset	Description
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	100X_F	RO	1	100BASE-TX Full-Duplex Mode When set, this bit indicates that the Ethernet Controller is capable of supporting 100BASE-TX Full-Duplex mode.
13	100X_H	RO	1	100BASE-TX Half-Duplex Mode When set, this bit indicates that the Ethernet Controller is capable of supporting 100BASE-TX Half-Duplex mode.
12	10T_F	RO	1	10BASE-T Full-Duplex Mode When set, this bit indicates that the Ethernet Controller is capable of 10BASE-T Full-Duplex mode.
11	10T_H	RO	1	10BASE-T Half-Duplex Mode When set, this bit indicates that the Ethernet Controller is capable of supporting 10BASE-T Half-Duplex mode.
10:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	ANEGC	RO	0	Auto-Negotiation Complete When set, this bit indicates that the auto-negotiation process has been completed and that the extended registers defined by the auto-negotiation protocol are valid.
4	RFAULT	RC	0	Remote Fault When set, this bit indicates that a remote fault condition has been detected. This bit remains set until it is read, even if the condition no longer exists.
3	ANEGA	RO	1	Auto-Negotiation When set, this bit indicates that the Ethernet Controller has the ability to perform auto-negotiation.

---

Bit/Field	Name	Type	Reset	Description
2	LINK	RO	0	Link Made When set, this bit indicates that a valid link has been established by the Ethernet Controller.
1	JAB	RC	0	Jabber Condition When set, this bit indicates that a jabber condition has been detected by the Ethernet Controller. This bit remains set until it is read, even if the jabber condition no longer exists.
0	EXTD	RO	1	Extended Capabilities When set, this bit indicates that the Ethernet Controller provides an extended set of capabilities that can be accessed through the extended register set.

### Register 19: Ethernet PHY Management Register 2 – PHY Identifier 1 (MR2), address 0x02

This register, along with **MR3**, provides a 32-bit value indicating the manufacturer, model, and revision information.

#### Ethernet PHY Management Register 2 – PHY Identifier 1 (MR2)

Base 0x4004.8000  
 Address 0x02  
 Type RO, reset 0x0161

Bit/Field	Name	Type	Reset	Description
15:0	OUI[21:6]	RO	0x0161	Organizationally Unique Identifier[21:6]  This field, along with the OUI[5:0] field in <b>MR3</b> , makes up the Organizationally Unique Identifier indicating the PHY manufacturer.

## Register 20: Ethernet PHY Management Register 3 – PHY Identifier 2 (MR3), address 0x03

This register, along with **MR2**, provides a 32-bit value indicating the manufacturer, model, and revision information.

### Ethernet PHY Management Register 3 – PHY Identifier 2 (MR3)

Base 0x4004.8000

Address 0x03

Type RO, reset 0xB410

Bit/Field	Name	Type	Reset	Description
15:10	OUI[5:0]	RO	0x2D	Organizationally Unique Identifier[5:0]  This field, along with the OUI[21:6] field in <b>MR2</b> , makes up the Organizationally Unique Identifier indicating the PHY manufacturer.
9:4	MN	RO	0x01	Model Number  The MN field represents the Model Number of the PHY.
3:0	RN	RO	0x0	Revision Number  The RN field represents the Revision Number of the PHY implementation.

## Register 21: Ethernet PHY Management Register 4 – Auto-Negotiation Advertisement (MR4), address 0x04

This register provides the advertised abilities of the Ethernet Controller used during auto-negotiation. Bits 8:5 represent the Technology Ability Field bits. This field can be overwritten by software to auto-negotiate to an alternate common technology. Writing to this register has no effect until auto-negotiation is re-initiated by setting the `RANEG` bit in the **MR0** register.

### Ethernet PHY Management Register 4 – Auto-Negotiation Advertisement (MR4)

Base 0x4004.8000  
Address 0x04  
Type R/W, reset 0x01E1

Reset	0	0	0	0	0	0	0	1	1	1	1	0	0	0	0	1

Bit/Field	Name	Type	Reset	Description
15	NP	RO	0	Next Page  When set, this bit indicates the Ethernet Controller is capable of Next Page exchanges to provide more detailed information on the PHY layer's capabilities.
14	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13	RF	R/W	0	Remote Fault  When set, this bit indicates to the link partner that a Remote Fault condition has been encountered.
12:9	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	A3	R/W	1	Technology Ability Field[3]  When set, this bit indicates that the Ethernet Controller supports the 100Base-TX full-duplex signaling protocol. If software wants to ensure that this mode is not used, this bit can be cleared and auto-negotiation re-initiated with the <code>RANEG</code> bit in the <b>MR0</b> register.
7	A2	R/W	1	Technology Ability Field[2]  When set, this bit indicates that the Ethernet Controller supports the 100Base-TX half-duplex signaling protocol. If software wants to ensure that this mode is not used, this bit can be cleared and auto-negotiation re-initiated with the <code>RANEG</code> bit in the <b>MR0</b> register.
6	A1	R/W	1	Technology Ability Field[1]  When set, this bit indicates that the Ethernet Controller supports the 10BASE-T full-duplex signaling protocol. If software wants to ensure that this mode is not used, this bit can be cleared and auto-negotiation re-initiated with the <code>RANEG</code> bit in the <b>MR0</b> register..

---

Bit/Field	Name	Type	Reset	Description
5	A0	R/W	1	Technology Ability Field[0]  When set, this bit indicates that the Ethernet Controller supports the 10BASE-T half-duplex signaling protocol. If software wants to ensure that this mode is not used, this bit can be cleared and auto-negotiation re-initiated with the <code>RANEG</code> bit in the <b>MRO</b> register..
4:0	S	RO	0x1	Selector Field  The <code>S</code> field encodes 32 possible messages for communicating between Ethernet Controllers. This field is hard-coded to 0x01, indicating that the Stellaris <sup>®</sup> Ethernet Controller is <i>IEEE 802.3</i> compliant.

## Register 22: Ethernet PHY Management Register 5 – Auto-Negotiation Link Partner Base Page Ability (MR5), address 0x05

This register provides the advertised abilities of the link partner's Ethernet Controller that are received and stored during auto-negotiation.

### Ethernet PHY Management Register 5 – Auto-Negotiation Link Partner Base Page Ability (MR5)

Base 0x4004.8000

Address 0x05

Type RO, reset 0x0000

Bit/Field	Name	Type	Reset	Description														
15	NP	RO	0	Next Page  When set, this bit indicates that the link partner's Ethernet Controller is capable of Next page exchanges to provide more detailed information on the Ethernet Controller's capabilities.														
14	ACK	RO	0	Acknowledge  When set, this bit indicates that the Ethernet Controller has successfully received the link partner's advertised abilities during auto-negotiation.														
13	RF	RO	0	Remote Fault  Used as a standard transport mechanism for transmitting simple fault information from the link partner.														
12:5	A[7:0]	RO	0x00	Technology Ability Field  The A[7:0] field encodes individual technologies that are supported by the Ethernet Controller. See the <b>MR4</b> register for definitions. Note that bits 12:9 describe functions that are not implemented on the Stellaris® Ethernet Controller. Refer to the IEEE 802.3 standard for definitions.														
4:0	S	RO	0x00	Selector Field  The S field encodes possible messages for communicating between Ethernet Controllers.  <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x00</td> <td>Reserved</td> </tr> <tr> <td>0x01</td> <td>IEEE Std 802.3</td> </tr> <tr> <td>0x02</td> <td>IEEE Std 802.9 ISLAN-16T</td> </tr> <tr> <td>0x03</td> <td>IEEE Std 802.5</td> </tr> <tr> <td>0x04</td> <td>IEEE Std 1394</td> </tr> <tr> <td>0x05–0x1F</td> <td>Reserved</td> </tr> </tbody> </table>	Value	Description	0x00	Reserved	0x01	IEEE Std 802.3	0x02	IEEE Std 802.9 ISLAN-16T	0x03	IEEE Std 802.5	0x04	IEEE Std 1394	0x05–0x1F	Reserved

4	PDF	RC	0	Parallel Detection Fault  When set, this bit indicates that more than one technology has been detected at link up. This bit is cleared when read.
3	LPNPA	RO	0	Link Partner is Next Page Able  When set, this bit indicates that the link partner is enabled to support next page.
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PRX	RC	0	New Page Received  When set, this bit indicates that a new page has been received from the link partner and stored. This bit remains set until the register is read.
0	LPANEGA	RO	0	Link Partner is Auto-Negotiation Able  When set, this bit indicates that the link partner is enabled to support auto-negotiation.

## Register 24: Ethernet PHY Management Register 16 – Vendor-Specific (MR16), address 0x10

This register contains a silicon revision identifier.

### Ethernet PHY Management Register 16 – Vendor-Specific (MR16)

Base 0x4004.8000

Address 0x10

Type RO, reset 0x0040

Bit/Field	Name	Type	Reset	Description
15:10	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:6	SR	RO	0x1	Silicon Revision Identifier This field contains four-bit identifier for the silicon revision.
5:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 25: Ethernet PHY Management Register 17 – Mode Control/Status (MR17), address 0x11

This register provides the means for controlling and observing various PHY layer modes.

### Ethernet PHY Management Register 17 – Mode Control/Status (MR17)

Base 0x4004.8000

Address 0x11

Type R/W, reset 0x0002

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved	FASTRIP	EDPD	reserved	LSQE	MDPB	FLPBK	FASTEST	reserved		REFCE	PADBP	FGLS	ENON	reserved	
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	RO	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit/Field	Name	Type	Reset	Description
15	reserved	R/W	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  <b>Important:</b> This bit must always be written with a 0 to ensure proper operation.
14	FASTRIP	R/W	0	10-BASE-T Fast Mode Enable  When set, this bit enables PHYT_10 test mode.
13	EDPD	R/W	0	Enable Energy Detect Power Down  When set, this bit enables the Energy Detect Power Down mode.
12	reserved	R/W	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  <b>Important:</b> This bit must always be written with a 0 to ensure proper operation.
11	LSQE	R/W	0	Low Squelch Enable  When set, this bit enables a lower threshold meaning more sensitivity to the signal levels.
10	MDPB	R/W	0	Management Data Preamble Bypass  When set, this bit enables SMI packets to be detected without preamble.
9	FLPBK	R/W	0	Far Loopback Mode  When set, this bit puts the PHY layer into Far Loopback Mode meaning that all the received packets are sent back simultaneously. This bit is only valid in 100BASE-TX operation when the PHY is in the RMII mode. When this bit is set, the system must supply a 50 MHz clock to the PHY layer. This mode works even when the ISO bit in the MR0 register is set.
8	FASTEST	R/W	0	Auto-Negotiation Test Mode  When set, this bit activates the Auto-Negotiation Test mode.

Bit/Field	Name	Type	Reset	Description
7:5	reserved	R/W	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  <b>Important:</b> This bit must always be written with a 0 to ensure proper operation.
4	REFCE	R/W	0	Reference Clock Enable  When set, this bit enables special filtering using a 50 MHz clock in 10BASE-T mode.
3	PADBP	R/W	0	PHY Address Bypass  When set, this bit causes the PHY layer to disregard the PHY address in an SMI access write.
2	FGLS	R/W	0	Force Good Link Status  When set, this bit forces the 100BASE-T link to be active.  <b>Note:</b> This bit should only be set when testing.
1	ENON	RO	1	Energy On  This bit indicates whether energy is detected on the line. When clear, this bit indicates that valid energy has not been detected on the line within 256 ms. This bit is set by a hardware reset, but is unaffected by a software reset.
0	reserved	R/W	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  <b>Important:</b> This bit must always be written with a 0 to ensure proper operation.

## Register 26: Ethernet PHY Management Register 27 –Special Control/Status (MR27), address 0x1B

This register shows the status of the 10BASE-T polarity.

### Ethernet PHY Management Register 27 –Special Control/Status (MR27)

Base 0x4004.8000

Address 0x1B

Type RO, reset -

Bit/Field	Name	Type	Reset	Description
15:5	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	XPOL	RO	0	Polarity State of 10 BASE-T When set, this bit indicates that the 10BASE-T is reversed polarity.
3:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 27: Ethernet PHY Management Register 29 – Interrupt Status (MR29), address 0x1D

This register contains information about the source of PHY layer interrupts.

### Ethernet PHY Management Register 29 – Interrupt Status (MR29)

Base 0x4004.8000

Address 0x1D

Type RO, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	EONIS	RO	0	ENERGYON Interrupt This bit is set when ENERGYON is the source of the interrupt.
6	ANCOMPIS	RO	0	Auto-Negotiation Complete Interrupt This bit is set when auto negotiation is complete.
5	RFLTIS	RO	0	Remote Fault Interrupt This bit is set when a remote fault has been detected.
4	LDIS	RO	0	Link Down Interrupt This bit is set when the Link Status has been negated.
3	LPACKIS	RO	0	Auto-Negotiation LP Acknowledge This bit is set when the PHY layer has received an acknowledge message from the link partner during auto-negotiation.
2	PDFIS	RO	0	Parallel Detection Fault This bit is set to indicate that a parallel detection fault has been detected by the PHY layer during auto negotiation.
1	PRXIS	RO	0	Auto Negotiation Page Received This bit is set to indicate that an auto negotiation page has been received from the link partner.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 28: Ethernet PHY Management Register 30 – Interrupt Mask (MR30), address 0x1E

This register enables interrupts to be generated by the various sources of PHY layer interrupts.

### Ethernet PHY Management Register 30 – Interrupt Mask (MR30)

Base 0x4004.8000  
Address 0x1E  
Type R/W, reset 0x0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
15:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	EONIM	R/W	0	ENERGYON Interrupt Enabled When set, this bit enables ENERGYON to generate a PHY layer interrupt.
6	ANCOMPIM	R/W	0	Auto-Negotiation Complete Interrupt Enabled When set, this bit enables the completion of auto negotiation generate a PHY layer interrupt.
5	RFLTIM	R/W	0	Remote Fault Interrupt Enabled When set, this bit enables a remote fault to generate a PHY layer interrupt.
4	LDIM	R/W	0	Link Down Interrupt Enabled When set, this bit enables a Link Status change to generate a PHY layer interrupt.
3	LPACKIM	R/W	0	Auto-Negotiation LP Acknowledge Enabled When set, this bit enables an acknowledge message received from a link partner during auto-negotiation to generate a PHY layer interrupt.
2	PDFIM	R/W	0	Parallel Detection Fault Enabled When set, this bit enables a parallel detection fault detection by the PHY layer during auto negotiation to generate a PHY layer interrupt.
1	PRXIM	R/W	0	Auto Negotiation Page Received Enabled When set, this bit enables a PHY layer interrupt when an auto negotiation page has been received from the link partner.
0	reserved	R/W	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 29: Ethernet PHY Management Register 31 – PHY Special Control/Status (MR31), address 0x1F

This register provides special control and status for the PHY layer.

### Ethernet PHY Management Register 31 – PHY Special Control/Status (MR31)

Base 0x4004.8000  
 Address 0x1F  
 Type R/W, reset 0x00040

Bit/Field	Name	Type	Reset	Description
15:13	reserved	R/W	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  <b>Important:</b> This bit field must always be written with a 0 to ensure proper operation.
12	AUTODONE	RO	0	Auto Negotiation Done  When set, this bit indicates that auto negotiation is complete.
11:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4:2	SPEED	RO	0x0	HCD Speed Value  [001] = 10BASE-T half duplex [010] = 100 BASE-T half duplex [101] = 10BASE-T full duplex [110] = 100BASE-T full duplex
1	reserved	R/W	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	SCRDIS	R/W	0	Scramble Disable  When set, this bit disables data scrambling.

## 20 Universal Serial Bus (USB) Controller

The Stellaris<sup>®</sup> USB controller operates as a full-speed or low-speed function controller during point-to-point communications with USB host, device, or OTG functions. The controller complies with the USB 2.0 standard, which includes suspend and resume signaling. Eight endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus six endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing.  $\mu$ DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device start-up. The controller complies with OTG standard's session request protocol (SRP) and host negotiation protocol (HNP).

The Stellaris<sup>®</sup> USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12 Mbps) and low-speed (1.5 Mbps) operation
- Integrated PHY
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory - one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive for up to 3 IN endpoints and 3 OUT endpoints
  - Burst requests
  - Channel requests asserted when FIFO contains required amount of data

## 20.1 Block Diagram

Figure 20-1. USB Module Block Diagram

## 20.2 Functional Description

**Note:** A 9.1-k $\Omega$  resistor should be connected between the `USB0RBIAS` and ground. The 9.1-k $\Omega$  resistor should have a 1% tolerance and should be located in close proximity to the `USB0RBIAS` pin. Power dissipation in the resistor is low, so a chip resistor of any geometry may be used.

The Stellaris<sup>®</sup> USB controller provides full OTG negotiation and support for connection to non-OTG peripherals or host controllers. It supports both the session request protocol (SRP) and the host negotiation protocol (HNP) to provide full OTG support. The session request protocol allows devices on the B side of a cable to request that the A side device turn on VBUS. The host negotiation protocol is used after the initial session request protocol has powered the bus and provides a method to determine which end of the cable will act as the host controller. When the device is connected to non-OTG peripherals or devices, the controller can detect which cable end was used and provides a register to indicate if the controller should act as the host or the device controller. This indication and the mode of operation are handled automatically by the USB controller. This auto-detection allows the system to use a single A/B connector instead of having both A and B connectors in the system. It also allows for full OTG negotiations with other OTG devices.

**Note:** When USB is used in the system, the minimum system frequency is 20 MHz.

### 20.2.1 Operation as a Device

This section describes the Stellaris<sup>®</sup> USB controller's actions when it is being used as a USB device. IN endpoints, OUT endpoints, entry into and exit from Suspend mode, and recognition of Start of Frame (SOF) are all described.

When in device mode, IN transactions are controlled by an endpoint's transmit interface and use the transmit endpoint registers for the given endpoint. OUT transactions are handled with an endpoint's receive interface and use the receive endpoint registers for the given endpoint.

When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be sized to be multiples of the maximum packet size (up to 64 bytes). For instance, if maximum packet size is 64 bytes, the FIFO should be configured to a multiple of 64-byte packets (64, 128, 192, or 256 bytes). This allows for efficient use of double buffering or packet splitting (described further in the following sections).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint for a USB device. However, in most cases the USB device should use the dedicated control endpoint on the USB controller's endpoint 0.

### 20.2.1.1 Endpoints

When operating as a device, there are two dedicated control endpoints (IN and OUT) and six configurable endpoints (3 IN and 3 OUT) that can be used for communications with a host controller. The endpoint number associated with an endpoint is directly related to its register designation. For example, when the host is communicating with endpoint 1, all events will occur in the endpoint 1 register interface.

Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions.

The remaining six endpoints can be configured as control, bulk, interrupt, or isochronous endpoints. They should be treated as three configurable IN and three configurable OUT endpoints. The three endpoint pairs (endpoint 1, 2, and 3) are not required to have the same type for their IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair could be a bulk endpoint, while the IN portion of that endpoint pair could be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

### 20.2.1.2 IN Transactions as a Device

When operating as a USB device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the three configurable IN endpoints are determined by the **USBTXFIFOADD** register. The maximum size of a data packet that may be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the **USBTXMAXPn** register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size. The USB controller also supports a special mode for bulk endpoints that allows automatic splitting of a larger FIFO into multiple packets that are maximum packet size transfers.

**Note:** The maximum packet size set for any endpoint must not exceed the FIFO size. The **USBTXMAXPn** register should not be written to while there is data in the FIFO as unexpected results may occur.

### Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the **USBTXFIFOSZ** register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the **TXRDY** bit in the **USBTXCSRLn** register needs to be set. If the **AUTOSET** bit in the **USBTXCSRHn** register is set, the **TXRDY** bit is automatically set when a maximum sized packet is loaded into the FIFO. For packet sizes less than the maximum, the **TXRDY** bit must be set manually. When the **TXRDY** bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both **TXRDY** and **FIFONE** are cleared and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

### Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the **TXRDY** bit in the **USBTXCSRLn** register needs to be set. If the **AUTOSET** bit in the **USBTXCSRHn** register is set, the **TXRDY** bit is automatically set when a maximum sized packet is loaded into the FIFO. For packet sizes less than the maximum, **TXRDY** must be set manually. When the **TXRDY** bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, **TXRDY** is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and **TXRDY** set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, **TXRDY** is cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the **FIFONE** bit at this point indicates how many packets may be loaded. If the **FIFONE** bit is set, then there is another packet in the FIFO and only one more packet can be loaded. If the **FIFONE** bit is clear, then there are no packets in the FIFO and two more packets can be loaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding **EPn** bit is set in the **USBTXDPKTBUFDIS** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

### Special Bulk Handling

The packets transferred in bulk operations are defined by the USB specification to be 8, 16, 32 or 64 bytes in size. For some system designs, however, it may be more convenient for the application software to write larger amounts of data to an endpoint in a single operation than can be transferred in a single USB operation.

To simplify this case, the Stellaris<sup>®</sup> USB controller includes a packet-splitting feature that allows larger data packets to be written to bulk transmit endpoints, which are then split into packets of an appropriate size for transfer across the USB bus. With this option, the **USBTXMAXPn** register uses the bottom 11 bits to define the payload for each individual transfer, while the top 5 bits define a multiplier. The application software can then write data packets of size multiplier × payload to the FIFO, which the USB controller then splits into individual packets of the stated payload for transmission over the USB bus. From the application software's point-of-view, the resulting operation does not differ from the transmission of a single USB packet except in the size of the packet written.

**Note:** Packet-splitting can only be used with bulk endpoints and, in accordance with the USB specification, the payload must be 8, 16, 32, or 64. The payload recorded in the **USBTXMAXPn** register must also match the **wMaxPacketSize** field of the Standard Endpoint Descriptor for the endpoint (see chapter 9 of the USB specification). The associated FIFO must also be large enough to accommodate the data packet prior to being split.

### 20.2.1.3 OUT Transactions as a Device

When in device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the three configurable OUT endpoints are determined by the **USBRXFIFOADD** register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the **USBRXMAXPn** register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size. The Stellaris<sup>®</sup> USB controller also supports a special mode for bulk endpoints that allows automatic splitting of a larger FIFO into multiple maximum packet size transfers.

**Note:** In all cases, the maximum packet size must not exceed the FIFO size.

#### **Single-Packet Buffering**

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the **RXRDY** and **FULL** bits in the **USBRXCSSLn** register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the **RXRDY** bit needs to be cleared in order to allow further packets to be received. This action also generates the acknowledge signaling to the host controller. If the **AUTOCL** bit in the **USBRXCSSLn** register is set and a maximum-sized packet is unloaded from the FIFO, the **RXRDY** and **FULL** bits are cleared automatically. For packet sizes less than the maximum, **RXRDY** must be cleared manually.

#### **Double-Packet Buffering**

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the **RXRDY** bit in the **USBRXCSSLn** register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

**Note:** The **FULL** bit in **USBRXCSSLn** is not set when the first packet is received. It is only set if a second packet is received and loaded into the receive FIFO.

After each packet has been unloaded, the **RXRDY** bit needs to be cleared in order to allow further packets to be received. If the **AUTOCL** bit in the **USBRXCSSLn** register is set and a maximum-sized packet is unloaded from the FIFO, the **RXRDY** bit is cleared automatically. For packet sizes less than the maximum, **RXRDY** must be cleared manually. If the **FULL** bit was set when **RXRDY** is cleared, the USB controller first clears the **FULL** bit. It then sets **RXRDY** again to indicate that there is another packet waiting in the FIFO to be unloaded.

**Note:** Double-packet buffering is disabled if an endpoint's corresponding **EPn** bit is set in the **USBRXDPKTBUFDIS** register. This bit is set by default, so it must be cleared to enable double-packet buffering.

#### **Special Bulk Handling**

The packets transferred in bulk operations are defined by the USB specification to be 8, 16, 32, or 64 bytes in size. For some system designs, however, it may be more convenient for the application software to read larger amounts of data from an endpoint in a single operation than can be transferred in a single USB operation.

To simplify this case, the Stellaris<sup>®</sup> USB controller includes a packet-combining feature that combines the packets received across the USB bus into larger data packets prior to being read by the application software. With this option, the **USBRXMAXPn** register uses the bottom 11 bits to define

the payload for each individual transfer, while the top 5 bits define a multiplier. The USB controller then combines the appropriate number of USB packets it receives into a single data packet of size multiplier × payload within the FIFO before asserting `RXRDY` to alert the application software that a packet in the FIFO is ready to be read. The size of the resulting packet is reported in the **USBXCOUNTn** register. From the application software's point-of-view, the resulting operation does not differ from the receipt of a single USB packet except in the size of the packet read.

**Note:** Packet-combining can only be used with bulk endpoints. The payload recorded in the **USBXMAXPn** register must also match the `wMaxPacketSize` field of the Standard Endpoint Descriptor for the endpoint (see chapter 9 of the USB specification). The associated FIFO must also be large enough to accommodate the combined data packet.

The `RXRDY` bit is only set when either the specified number of packets have been received or a “short” USB packet is received (that is, a packet of less than the specified payload for the endpoint). If a protocol is being used in which the endpoint receives bulk transfers that are a multiple of the recorded payload size with no short packet to terminate it, the **USBXMAXPn** register should not be programmed to expect more packets than there are in the transfer (otherwise, the software will not be interrupted at the end of the transfer).

#### 20.2.1.4 Scheduling

The device has no control over the scheduling of transactions as this is determined by the host controller. The Stellaris® USB controller can set up a transaction at any time. The USB controller will wait for the request from the host controller and generate an interrupt when the transaction is complete or if it was terminated due to some error. If the host controller makes a request and the device controller is not ready, the USB controller sends a busy response (NAK) to all requests until it is ready.

#### 20.2.1.5 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the host controller: when the USB controller automatically stalls a control transfer and unexpected zero length OUT data packets.

##### ***Stalled Control Transfer***

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the `DATAEND` bit in the **USBCSRL0** register has been set.
2. The host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the host sends an IN token (instead of an OUT token) after the CPU has cleared `TXRDY` and set `DATAEND` in response to the ACK issued by the host to what should have been the last packet.
3. The host sends more than **USBXMAXPn** bytes of data with an OUT data token.
4. The host sends more than a zero length data packet for the OUT status phase.

### Zero Length OUT Data Packets

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the device request has been transferred.

However, if the host sends a zero-length OUT data packet before the entire length of device request has been transferred, it is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the `SETUP` bit in the `USBCSRL0` register.

### Setting the Device Address

When a host device is attempting to enumerate the USB device, it requests that the device change its address from zero to some other value. The address is changed by writing the value that the host requested to the `USBFADDR` register. However, care should be taken when writing to `USBFADDR` to avoid changing the address before the transaction is complete. This register should only be set after the `SET_ADDRESS` command is complete. Like all control transactions, the transaction is only complete after the device has left the `STATUS` phase. In the case of a `SET_ADDRESS` command, the transaction is completed by responding to the IN request from the host with a zero-byte packet. Once the device has responded to the IN request, the `USBFADDR` register should be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

**Note:** If the `USBFADDR` register is set to the new value as soon as the device receives the OUT transaction with the `SET_ADDRESS` command in the packet, it changes the address during the control transfer. In this case, the device does not receive the IN request that allows the USB transaction to exit the `STATUS` phase of the control transfer because it is sent to the old address. As a result, the host does not get a response to the IN request, and the host fails to enumerate the device.

## 20.2.1.6 Device Mode Suspend

When no activity has occurred on the USB bus for 3 ms, the USB controller automatically enters Suspend mode. If the Suspend interrupt has been enabled, an interrupt is generated at this time. When in Suspend mode, the PHY also goes into Suspend mode. When Resume signaling is detected, the USB controller exits Suspend mode and takes the PHY out of Suspend. If the Resume interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit Suspend mode by setting the `RESUME` bit in the `USBPOWER` register. When this bit is set, the USB controller exits Suspend mode and drives Resume signaling onto the bus. The `RESUME` bit is cleared after 10 ms (a maximum of 15 ms) to end Resume signaling.

To meet USB power requirements, the controller can be put into Deep Sleep. This keeps the controller in a static state.

## 20.2.1.7 Start-of-Frame

When the USB controller is operating in device mode, it receives a Start-Of-Frame packet from the host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the `USBFAME` register and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, it expects one every millisecond. If no SOF packet is received after 1.00358 ms, it is assumed that the packet has been lost and the `USBFAME` register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

### 20.2.1.8 USB Reset

When the USB controller is in device mode and a reset condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the **USBFADDR** register.
- Clears the **USBEPIDX** register.
- Flushes all endpoint FIFOs.
- Clears all control/status registers.
- Enables all endpoint interrupts.
- Generates a reset interrupt.

When the application software driving the USB controller receives a reset interrupt, it closes any open pipes and waits for bus enumeration to begin.

### 20.2.1.9 Connect/Disconnect

The USB controller connection to the USB bus is controlled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the **SOFTCONN** bit of the **USBPOWER** register. When this **SOFTCONN** bit is set, the PHY is placed in its normal mode and the **USB0DP/USB0DM** lines of the USB bus are enabled. At the same time, the USB controller is placed into a state, in which it will not respond to any USB signaling except a USB reset.

When the **SOFTCONN** bit is cleared, the PHY is put into non-driving mode, **USB0DP** and **USB0DM** are tristated, and the USB controller appears to other devices on the USB bus as if it has been disconnected. This is the default so the USB controller appears disconnected until the **SOFTCONN** bit has been set. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete and the system is ready to perform enumeration before connecting to the USB. Once the **SOFTCONN** bit has been set, the USB controller can be disconnected by clearing this bit.

**Note:** The USB controller does not generate an interrupt when the device is connected to the host. However, an interrupt is generated when the host terminates a session.

## 20.2.2 Operation as a Host

When the Stellaris<sup>®</sup> USB controller is operating in host mode, it can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, isochronous, and interrupt transactions are supported. This section describes the USB controller's actions when it is being used as a USB host. Configuration of IN endpoints, OUT endpoints, entry into and exit from Suspend mode, and reset are all described.

When in host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in device mode, the FIFOs for endpoints should take into account the maximum packet size for an endpoint.

- **Bulk.** Bulk endpoints should be sized to be multiples of the maximum packet size (up to 64 bytes). For instance, if maximum packet size is 64 bytes, the FIFO should be configured to a multiple of 64-byte packets (64, 128, 192, or 256 bytes). This allows for efficient use of double buffering or packet splitting (described further in the following sections).
- **Interrupt.** Interrupt endpoints should be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- **Isochronous.** Isochronous endpoints are more flexible and can be up to 1023 bytes.
- **Control.** It is also possible to specify a separate control endpoint to communicate with a device. However, in most cases the USB controller should use the dedicated control endpoint to communicate with a device's endpoint 0.

### 20.2.2.1 Endpoints

The endpoint registers are used to control the USB endpoint interfaces used to communicate with device(s) that are connected. There is a dedicated control IN endpoint, a dedicated control OUT endpoint, three configurable OUT endpoints, and three configurable IN endpoints.

The dedicated control interface can only be used for control transactions to endpoint 0 of devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, interrupt, or isochronous device endpoints.

These USB interfaces can be used to simultaneously schedule as many as three independent OUT and three independent IN transactions to any endpoints on any device. The IN and OUT controls are paired in three sets of registers. However, they can be configured to communicate with different types of endpoints and different endpoints on devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a device's bulk OUT endpoint 1, while the IN portion is communicating with a device's interrupt IN endpoint 2.

Before accessing any device, whether for point-to-point communications or for communications via a hub, the relevant **USBRXFUNCADDR<sub>n</sub>** or **USBTXFUNCADDR<sub>n</sub>** registers need to be set for each receive or transmit endpoint to record the address of the device being accessed.

The USB controller also supports connections to devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. This includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

### 20.2.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in Device mode except that the transaction first needs to be initiated by setting the **REQPKT** bit in **USBCSRL0**. This indicates to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target device. When the packet is received and placed in the receive FIFO, the **RXRDY** bit in **USBCSRL0** is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, **RXRDY** should be cleared. The **AUTOCL** bit in the **USBRXCSRH<sub>n</sub>** register can be used to have **RXRDY** automatically cleared when a maximum-sized packet has been unloaded from the FIFO. There is also an **AUTORQ** bit in **USBRXCSRH<sub>n</sub>** which causes the **REQPKT** bit to be automatically set when the **RXRDY** bit is cleared. The **AUTOCL** and

AUTORQ bits can be used with  $\mu$ DMA accesses to perform complete bulk transfers without main processor intervention. When the RXRDY bit is cleared, the controller will send an acknowledge to the device. When there is a known number of packets to be transferred, the **USBRQPKTCOUNTn** register associated with the endpoint should be set to the number of packets to be transferred. The USB controller decrements the value in the **USBRQPKTCOUNTn** register following each request. When the **USBRQPKTCOUNTn** value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, **USBRQPKTCOUNTn** should be left set to zero. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than MaxP) such as may occur at the end of a bulk transfer.

If the device responds to a bulk or interrupt IN token with a NAK, the USB host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target device responds with a STALL, however, the USB host controller does not retry the transaction but interrupts the CPU with the STALLED bit in the **USBCSRL0** register set. If the target device does not respond to the IN token within the required time, or there was a CRC or bit-stuff error in the packet, the USB host controller retries the transaction. If after three attempts the target device has still not responded, the USB host controller clears the REQPKT bit and interrupts the CPU by setting the ERROR bit in the **USBCSRL0** register.

### 20.2.2.3 Out Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in Device mode. The TXRDY bit in the **USBTXCSSLn** register needs to be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the **USBTXCSSLn** register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO. Furthermore, AUTOSET can be used with a  $\mu$ DMA controller to perform complete bulk transfers without software intervention.

If the target device responds to the OUT token with a NAK, the USB host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the **USBTXCSSLn** register. If the target device does not respond to the OUT token within the required time, or there was a CRC or bit-stuff error in the packet, the USB host controller retries the transaction. If after three attempts the target device has still not responded, the USB controller flushes the FIFO and interrupts the main processor by setting the ERROR bit in the **USBTXCSSLn** register.

### 20.2.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB host controller. The host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a device is not responding. Isochronous endpoints can be scheduled from every frame to every  $2^{16}$  frames, in powers of 2.

The USB controller maintains a frame counter. If the target device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target device is a low-speed device, a 'K' state is transmitted on the bus to act as a "keep-alive" to stop the low-speed device from going into Suspend mode.

After the SOF packet has been transmitted, the USB host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An active isochronous or interrupt transaction starts only if it is found on the first transaction scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. This ensures that only one interrupt or isochronous transaction occurs per endpoint every  $n$  frames, where  $n$  is the interval set via the **USBTXINTERVAL $n$**  or **USBRXINTERVAL $n$**  register for that endpoint.

An active bulk transaction starts immediately, provided there is sufficient time left in the frame to complete the transaction before the next SOF packet is due. If the transaction needs to be retried (for example, because a NAK was received or the target device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This ensures that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The core also allows the user to specify a limit to the length of time for NAKs to be received from a target device before the endpoint times out.

#### 20.2.2.5 USB Hubs

The following setup requirements apply to the USB host controller only if it is used with a USB hub. When a full- or low-speed device is connected to the USB controller via a USB 2.0 hub, details of the hub address and the hub port also need to be recorded in the corresponding **USBRXHUBADDR $n$**  and **USBRXHUBPORT $n$**  or the **USBTXHUBADDR $n$**  and **USBTXHUBPORT $n$**  registers. In addition, the speed at which the device operates (full or low) needs to be recorded in the **USBTYPEn** (endpoint 0), **USBTXTYPEn**, or **USBRXTYPEn** registers for each endpoint that is accessed by the device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB devices. To maximize the number of devices supported, the USB host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to device functions need to be made following the completion of any on-going transactions on the endpoints affected.

#### 20.2.2.6 Babble

The USB host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. It also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB host controller assumes that the target device to which it is connected has malfunctioned and the USB controller suspends all transactions and generates a babble interrupt.

#### 20.2.2.7 Host Suspend

If the **SUSPEND** bit in the **USBPOWER** register is set, the USB host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit Suspend mode, the **RESUME** bit is set and the **SUSPEND** bit is cleared. While the **RESUME** bit is High, the USB host controller generates Resume signaling on the bus. After 20 ms, the **RESUME** bit should be cleared, at which point the frame counter and transaction scheduler start. The host supports the detection of a remote wake-up.

#### 20.2.2.8 USB Reset

If the **RESET** bit in the **USBPOWER** register is set, the USB host controller generates USB Reset signaling on the bus. The **RESET** bit should be set for at least 20 ms to ensure correct resetting of the target device. After the CPU has cleared the bit, the USB host controller starts its frame counter and transaction scheduler.

### 20.2.2.9 Connect/Disconnect

A session is started by setting the `SESSION` bit in the `USBDEVCTL` register. This enables the USB controller to wait for a device to be connected. When a device is detected, a connect interrupt is generated. The speed of the device that has been connected can be determined by reading the `USBDEVCTL` register where the `FSDEV` bit is High for a full-speed device and the `LSDEV` bit is High for a low-speed device. The USB controller should generate a reset to the device and then the USB host controller can begin device enumeration. If the device is disconnected while a session is in progress, a disconnect interrupt is generated.

## 20.2.3 OTG Mode

In order to conserve power, the USB On-The-Go (OTG) supplement allows VBus to only be powered up when required and to be turned off when the bus is not in use. VBus is always supplied by the A device on the bus. The USB OTG controller determines whether it is the A device or the B device by sampling the ID input from the PHY. This signal is pulled Low when an A-type plug is sensed (signifying that the USB OTG controller should act as the A device) but taken High when a B-type plug is sensed (signifying that the USB controller is a B device).

### 20.2.3.1 Starting a Session

When the USB OTG controller needs to start a session, the `SESSION` bit should be set in the `USBDEVCTL` register. The USB OTG controller then enables ID pin sensing. The ID input is either taken Low if an A-type connection is detected or High if a B-type connection is detected. The `DEV` bit in the `USBDEVCTL` register is also set to indicate whether the USB OTG controller has adopted the role of the A device or the B device.

If the USB OTG controller is the A device, then the USB OTG controller enters Host mode (the A device is always the default host), turns on VBus, and waits for VBus to go above the VBus Valid threshold, as indicated by the `VBUS` bit in the `USBDEVCTL` register going to 0x3. The USB OTG controller then waits for a peripheral to be connected. When a peripheral is detected, a Connect interrupt is signaled and either the `FSDEV` or `LSDEV` bit in the `USBDEVCTL` register is set, depending whether a full-speed or a low-speed peripheral is detected. The USB controller then issues a reset to the connected device. The `SESSION` bit in the `USBDEVCTL` register is cleared to end a session. The USB OTG controller will also automatically end the session if babble is detected.

If the USB OTG controller is the B device, then the USB OTG controller requests a session using the Session Request Protocol defined in the USB On-The-Go supplement, that is, it will first discharge VBus. Then when VBus has gone below the Session End threshold (`VBUS` bit in the `USBDEVCTL` register goes to 0x0) and the line state has been a single-ended zero for > 2 ms, the USB OTG controller pulses the data line, then pulses VBus. At the end of the session, the `SESSION` bit is cleared either by the USB OTG controller or by the application software. The USB OTG controller then causes the PHY to switch out the pull-up resistor on D+. This signals the A device to end the session.

### 20.2.3.2 Detecting Activity

When the other device of the OTG set-up wishes to start a session, it either raises VBus above the Session Valid threshold if it is the A device, or if it is the B device, it pulses the data line then pulses VBus. Depending on which of these actions happens, the USB controller can determine whether it is the A device or the B device in the current set-up and act accordingly. If VBus is raised above the Session Valid threshold, then the USB controller is the B device. The USB controller sets the `SESSION` bit in the `USBDEVCTL` register. When Reset signaling is detected on the bus, a Reset interrupt is signaled, which is interpreted as the start of a session.

The USB controller is in device mode at this point as the B device is the default mode. At the end of the session, the A device turns off the power to VBus. When VBus drops below the Session Valid threshold, the USB controller detects this and clears the `SESSION` bit to indicate that the session has ended. This causes a disconnect interrupt to be signaled. If data line and VBus pulsing is detected, then the USB controller is the A device. It generates a Session Request interrupt to indicate that the B device is requesting a session. The `SESSION` bit in the **USBDEVCTL** register should then be set to start a session.

### 20.2.3.3 Host Negotiation

When the USB controller is the A device, ID is Low, and it automatically enters Host mode when a session starts. When the USB controller is the B device, ID is High, and it automatically enters Device mode when a session starts. However, the CPU can request that the USB controller become the host by setting the `HOSTREQ` bit in the **USBDEVCTL** register. This bit can be set either at the same time as requesting a Session Start by setting the `SESSION` bit in the **USBDEVCTL** register, or at any time after a session has started. When the USB controller next enters Suspend mode, assuming the `HOSTREQ` bit remains set, it enters Host mode and begins host negotiation (as specified in the USB On-The-Go supplement) by causing the PHY to disconnect the pull-up resistor on the D+ line. This causes the A device to switch to Device mode and connect its own pull-up resistor. When the USB controller detects this, it generates a Connect interrupt. It also sets the `RESET` bit in the **USBPOWER** register to begin resetting the A device. The USB controller begins this reset sequence automatically to ensure that reset is started as required within 1 ms of the A device connecting its pull-up resistor. The main processor should wait at least 20 ms, then clear the `RESET` bit and enumerate the A device.

When the USB OTG controller B device has finished using the bus, it goes into Suspend mode by setting the `SUSPEND` bit in the **USBPOWER** register. The A device detects this and either terminates the session or reverts to Host mode. If the A device is USB OTG controller, it generates a Disconnect interrupt.

### 20.2.4 DMA Operation

The USB peripheral provides an interface connected to the  $\mu$ DMA controller. The DMA operation of the USB is enabled through the **USBTXCSRHn** and **USBRXCSRHn** registers, for the TX and RX channels respectively. When DMA operation is enabled, the USB asserts a DMA request on the enabled receive or transmit channel when the associated FIFO can transfer data. When either FIFO can transfer data, the burst request for that channel is asserted. The  $\mu$ DMA channel must be configured with an arbitration size that matches the size of the USB FIFO, and the size of the  $\mu$ DMA transfer must be restricted to whole multiples of the size of the USB FIFO. Both read and write transfers of the USB FIFOs using  $\mu$ DMA should be configured in this manner. For example, if the USB endpoint is configured with a FIFO size of 64 bytes, the  $\mu$ DMA channel must be configured with an arbitration size of 64. The  $\mu$ DMA channel can be used to transfer 64 bytes to or from the endpoint FIFO. If the number of bytes to transfer is less than 64, then a programmed I/O method must be used to copy the data to or from the FIFO.

If DMA is enabled, then the  $\mu$ DMA controller triggers an interrupt when a transfer is complete. The interrupt occurs on the USB interrupt vector. Therefore, if interrupts are used for USB operation and DMA is enabled, the USB interrupt handler must be designed to handle the  $\mu$ DMA completion interrupt.

Care must be taken when using a DMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of the `RxMaxP` bit in the **USBRXCSRHn** register. The `RXRDY` bit is cleared as follows.

**Table 20-1. Remainder (RxMaxP/4)**

Value	Description
0	RxMaxP = 64 bytes
1	RxMaxP = 61 bytes
2	RxMaxP = 62 bytes
3	RxMaxP = 63 bytes

**Table 20-2. Actual Bytes Read**

Value	Description
0	RxMaxP
1	RxMaxP+3
2	RxMaxP+2
3	RxMaxP+1

**Table 20-3. Packet Sizes That Will Clear RXRDY**

Value	Description
0	RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3
1	RxMaxP
2	RxMaxP, RxMaxP-1
3	RxMaxP, RxMaxP-1, RxMaxP-2

To enable DMA operation for the endpoint receive channel, the `DMAEN` bit of the **USBRXCSRHn** register should be set. To enable DMA operation for the endpoint transmit channel, the `DMAEN` bit of the **USBTXCSRHn** register should be set.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 226 for more details about programming the  $\mu$ DMA controller.

## 20.3 Initialization and Configuration

To use the USB Controller, the peripheral clock must be enabled by via the **RCGC2** register. See page 179. In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register in the System Control module. See page 179. To find out which GPIO port to enable, refer to Table 25-5 on page 990.

The initial configuration in all cases requires that the processor enable the USB controller and USB controller’s physical layer interface (PHY) before setting any registers. The next step is to enable the USB PLL so that the correct clocking is provided to the PHY. To ensure that voltage is not supplied to the bus incorrectly, the external power control signal, `USB0EPEN`, should be de-asserted on start up. This requires setting the `USB0EPEN` and `USB0PFLT` pins to be controlled by the USB controller and not have their default GPIO behavior.

The VBUS sense and ID pins (`USB0VBUS` and `USB0ID`) do not require any configuration as they are dedicated pins for the USB controller. In OTG mode, these pins directly connect to the USB connector’s VBUS and ID signals. In Host and Device modes, these pins must be tied to appropriate voltage levels. `USB0VBUS` must be tied to 5 V (4.75-5.25V). `USB0ID` must be tied Low for USB Host operation or tied High for USB Device Operation. These pins should not be used as GPIOs while using the USB controller as it may cause unexpected behavior in the controller.

### 20.3.1 Pin Configuration

When using the device controller portion of the USB controller in a system that also provides host functionality, the power to VBUS must be disabled to allow the external host controller to supply power. Usually, the `USB0EPEN` signal is used to control the external regulator and should be de-asserted to avoid having two devices driving the `USB0VBUS` power pin on the USB connector.

When the USB controller is acting as a host, it is in control of two signals that are attached to an external voltage supply that provides power to VBUS. The host controller uses the `USB0EPEN` signal to enable or disable power to the `USB0VBUS` pin on the USB connector. There is also an input pin, `USB0PFLT`, which provides feedback when there has been a power fault on VBUS. The `USB0PFLT` signal can be configured to either automatically de-assert the `USB0EPEN` signal to disable power, and/or it can generate an interrupt to the main processor to allow it to handle the power fault condition. The polarity and actions related to both `USB0EPEN` and `USB0PFLT` are fully configurable in the USB controller. The controller also provides interrupts on device insertion and removal to allow the host controller code to respond to these external events.

### 20.3.2 Endpoint Configuration

In order to start communication on host or device mode, the endpoint registers must first be configured. In Host mode, this provides a connection between an endpoint register and an endpoint on a device. In Device mode, this provides the setup for a given endpoint before enumerating to the host controller.

In both cases, the endpoint 0 configuration is limited as this is a fixed function, fixed FIFO size endpoint. In Device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In Device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the host controller. In Host mode, the endpoints must be configured to operate as control, bulk, interrupt or isochronous mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. Isochronous endpoints can have packets with up to 1023 bytes per packet. In either mode, the maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes in use by endpoint 0. The endpoint's FIFO does not have to be the same size as the maximum packet size in all cases as the controller can automatically split for bulk transactions if the FIFO is larger than the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a device, the USB device controllers' soft connect should be enabled when the device is ready to start communications. This indicates to the host controller that the device is ready to start the enumeration process. If operating as a host controller, the device soft connect should be disabled and power should be provided to VBUS via the `USB0EPEN` signal.

## 20.4 Register Map

Table 20-4 on page 786 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 179).

**Table 20-4. Universal Serial Bus (USB) Controller Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	USBFADDR	R/W	0x00	USB Device Functional Address	790
0x001	USBPOWER	R/W	0x20	USB Power	791
0x002	USBTXIS	RO	0x0000	USB Transmit Interrupt Status	793

## 20.5 Register Descriptions

The LM3S9792 USB controller is configured to the communication mode specified in the `USB0` bit field in the **DC6** register (page 147):

- On-The-Go (OTG) (`USB0` set to 0x3)

### Register 1: USB Device Functional Address (USBFADDR), offset 0x000

**Device**

**USBFADDR** is an 8-bit register that should be written with the 7-bit address of the device part of the transaction.

When the USB controller is being used in Device mode (`HOST` bit in **USBDEVCTL** register is 0), this register should be written with the address received through a `SET_ADDRESS` command, which is then used for decoding the function address in subsequent token packets.

**Important:** See the section called “Setting the Device Address” on page 777 for special considerations when writing this register.

#### USB Device Functional Address (USBFADDR)

Base 0x4005.0000  
 Offset 0x000  
 Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	FUNCADDR	R/W	0x00	Function Address Function Address of Device as received through <code>SET_ADDRESS</code> .

## Register 2: USB Power (USBPOWER), offset 0x001

Host

USBPOWER is an 8-bit register that is used for controlling Suspend and Resume signaling, and some basic operational aspects of the USB controller.

Device

### Host Mode

#### USB Power (USBPOWER)

Base 0x4005.0000  
Offset 0x001  
Type R/W, reset 0x20

Bit/Field	Name	Type	Reset	Description
7:4	reserved	RO	0x02	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	RESET	R/W	0	Reset  This bit is set to enable Reset signaling on the bus and cleared to end Reset signaling on the bus.
2	RESUME	R/W	0	Resume Signaling  Set by the CPU to generate Resume signaling when the device is in Suspend mode. The CPU should clear this bit after 20 ms.
1	SUSPEND	R/W1S	0	Suspend Mode  This bit is written to 1 by the CPU to enter Suspend mode. Writing a 0 does nothing.
0	PWRDNPHY	R/W	0	Power Down PHY  Set by the CPU to power down the internal USB PHY.

### Device Mode

#### USB Power (USBPOWER)

Base 0x4005.0000  
Offset 0x001  
Type R/W, reset 0x20

Bit/Field	Name	Type	Reset	Description
7	ISOUP	R/W	0	<p>ISO Update</p> <p>When set by the CPU, the USB controller waits for an SOF token from the time <code>TXRDY</code> is set before sending the packet. If an IN token is received before an SOF token, then a zero-length data packet is sent.</p> <p><b>Note:</b> Only valid for isochronous transfers.</p>
6	SOFTCONN	R/W	0	<p>Soft Connect/Disconnect</p> <p>The USB D+/D- lines are enabled when this bit is set by the CPU, and tri-stated when this bit is cleared by the CPU.</p>
5:4	reserved	RO	0x2	<p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>
3	RESET	RO	0	<p>Reset</p> <p>This bit is set when Reset signaling is present on the bus.</p>
2	RESUME	R/W	0	<p>Resume Signaling</p> <p>Set by the CPU to generate Resume signaling when the device is in Suspend mode. The CPU should clear this bit after 10 ms (a maximum of 15 ms) to end Resume signaling.</p>
1	SUSPEND	RO	0	<p>Suspend Mode</p> <p>This bit is set on entry into Suspend mode. It is cleared when the CPU reads the interrupt register or sets the <code>RESUME</code> bit above.</p>
0	PWRDNPHY	R/W	0	<p>Power Down PHY</p> <p>Set by the CPU to power down the internal USB PHY.</p>

### Register 3: USB Transmit Interrupt Status (USBTXIS), offset 0x002

Host

Device

**USBTXIS** is a 16-bit read-only register that indicates which interrupts are currently active for endpoint 0 and the transmit endpoints 1–3. The meaning of the  $EP_n$  bits in this register are based on the mode of the device. For the  $EP_1$ ,  $EP_2$  and  $EP_3$  bits, these bits always indicate that the USB controller is sending data; however, in Host mode, these are the three configurable OUT endpoints; while in device mode, these are the three configurable IN endpoints. The  $EP_0$  bit is special in Host and Device modes and indicates that either a control IN or control OUT endpoint has generated an interrupt.

**Note:** Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

#### USB Transmit Interrupt Status (USBTXIS)

Base 0x4005.0000

Offset 0x002

Type RO, reset 0x0000

2	EP2	RO	0	TX Endpoint 2 Interrupt
1	EP1	RO	0	TX Endpoint 1 Interrupt
0	EP0	RO	0	TX and RX Endpoint 0 Interrupt

### Register 4: USB Receive Interrupt Status (USBRXIS), offset 0x004

**Host**

**USBRXIS** is a 16-bit read-only register that indicates which of the interrupts for receive endpoints 1–3 are currently active.

**Device**

**Note:** Bits relating to endpoints that have not been configured always return 0. Note also that all active interrupts are cleared when this register is read.

#### USB Receive Interrupt Status (USBRXIS)

Base 0x4005.0000  
 Offset 0x004  
 Type RO, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EP3	RO	0	RX Endpoint 3 Interrupt
2	EP2	RO	0	RX Endpoint 2 Interrupt
1	EP1	RO	0	RX Endpoint 1 Interrupt
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

**Register 5: USB Transmit Interrupt Enable (USBTXIE), offset 0x006**

Host

Device

**USBTXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in **USBTXIS**. When a bit in **USBTXIE** is set to 1, the USB interrupt to the processor is asserted when the corresponding interrupt bit in the **USBTXIS** register is set. When a bit is cleared to 0, the interrupt in **USBTXIS** is still set but the USB interrupt to the processor is not asserted. On reset, the bits corresponding to endpoint 0 and transmit endpoints 1-3 are set to 1, while the remaining bits are set to 0.

USB Transmit Interrupt Enable (USBTXIE)

Base 0x4005.0000  
 Offset 0x006  
 Type R/W, reset 0x000F

Bit/Field	Name	Type	Reset	Description

2	EP2	R/W	1	TX Endpoint 2 Interrupt Enable
1	EP1	R/W	1	TX Endpoint 1 Interrupt Enable
0	EP0	R/W	1	TX and RX Endpoint 0 Interrupt Enable

### Register 6: USB Receive Interrupt Enable (USBRXIE), offset 0x008

Host

Device

**USBRXIE** is a 16-bit register that provides interrupt enable bits for the interrupts in **USBRXIS**. When a bit in **USBRXIE** is set to 1, the USB interrupt to the processor is asserted when the corresponding interrupt bit in the **USBRXIS** register is set. When a bit is cleared to 0, the interrupt in **USBRXIS** is still set but the USB interrupt to the processor is not asserted. On reset, the bits corresponding to receive endpoints 1-3 are set to 1, while the remaining bits are set to 0.

#### USB Receive Interrupt Enable (USBRXIE)

Base 0x4005.0000  
 Offset 0x008  
 Type R/W, reset 0x000E

Bit/Field	Name	Type	Reset	Description
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EP3	R/W	1	RX Endpoint 3 Interrupt Enable
2	EP2	R/W	1	RX Endpoint 2 Interrupt Enable
1	EP1	R/W	1	RX Endpoint 1 Interrupt Enable
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

## Register 7: USB General Interrupt Status (USBIS), offset 0x00A

OTG

**USBIS** is an 8-bit read-only register that indicates which USB interrupts are currently active. All active interrupts are cleared when this register is read.

Host

Device

### Host Mode

#### USB General Interrupt Status (USBIS)

Base 0x4005.0000

6	FIFOACC	R/W1S	0	FIFO Access The CPU sets this bit to transfer the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO. It is cleared automatically.
5	FORCEFS	R/W	0	Force Full Speed The CPU sets this bit to force the USB controller into Full-Speed mode when it receives a USB reset. When 0, the USB controller operates at Low Speed.
4:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

**Register 12: USB FIFO Endpoint 0 (USBFIFO0), offset 0x020****Register 13: USB FIFO Endpoint 1 (USBFIFO1), offset 0x024****Register 14: USB FIFO Endpoint 2 (USBFIFO2), offset 0x028****Register 15: USB FIFO Endpoint 3 (USBFIFO3), offset 0x02C****Host**

These 32-bit registers provide an address for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the Transmit FIFO for the corresponding endpoint. Reading from these addresses unloads data from the Receive FIFO for the corresponding endpoint.

**Device**

Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of access is allowed provided the data accessed is contiguous. All transfers associated with one packet must be of the same width so that the data is consistently byte-, word- or double-word-aligned. However, the last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or double-packet buffering. Burst writing of multiple packets is not supported as flags need to be set after each packet is written.

Following a STALL response or a transmit error on endpoint 1–3, the associated FIFO is completely flushed.

**USB FIFO Endpoint 0 (USBFIFO0)**

Writing to this register loads the data into the Transmit FIFO and reading unloads data from the Receive FIFO.

**Register 16: USB Device Control (USBDEVCTL), offset 0x060**

**OTG**

**USBDEVCTL** is an 8-bit register used for controlling and monitoring the USB VBus line. If the PHY is suspended, no PHY clock is received and the VBus is not sampled.

**Host**

**USBDEVCTL** provides the status information for the current operating mode (host or device) of the USB controller. If the USB controller is in host mode, this register also indicates if a full- or low-speed device has been connected.

**Device**

**Host Mode**

**Register 21: USB Connect Timing (USBCONTIM), offset 0x07A**

OTG

This 8-bit configuration register allows some delays to be specified.

Host

USB Connect Timing (USBCONTIM)

Base 0x4005.0000

Offset 0x07A

Type R/W, reset 0x5C

Device

Bit/Field	Name	Type	Reset	Description
7:4	WTCON	R/W	0x5	Connect Wait  Sets the wait to be applied to allow for the user's connect/disconnect filter, in units of 533.3 ns. (The default setting corresponds to 2.667 $\mu$ s.)
3:0	WTID	R/W	0xC	Wait ID  Set the delay to be applied from the enable of the ID detection to when the ID value is valid, in units of 4.369 ms. (The default setting corresponds to 52.43 ms.)

### Register 22: USB OTG VBus Pulse Timing (USBVPLEN), offset 0x07B

**OTG**

This 8-bit configuration register sets the duration of the VBus pulsing charge.

USB OTG VBus Pulse Timing (USBVPLEN)

Base 0x4005.0000  
 Offset 0x07B  
 Type R/W, reset 0x3C

Bit/Field	Name	Type	Reset	Description
7:0	VPLEN	R/W	0x3C	VBus Pulse Length  Sets the duration of the VBus pulsing charge in units of 546.1 $\mu$ s. (The default setting corresponds to 32.77 ms.)

## Register 23: USB Full-Speed Last Transaction to End of Frame Timing (USBFSEOF), offset 0x07D

### Host

This 8-bit configuration register sets the minimum time gap that is to be allowed between the start of the last transaction and the EOF for full-speed transactions.

### Device

USB Full-Speed Last Transaction to End of Frame Timing (USBFSEOF)

Base 0x4005.0000

Offset 0x07D

Type R/W, reset 0x77

Bit/Field	Name	Type	Reset	Description
7:0	FSEOFG	R/W	0x77	Full-Speed End-of-Frame Gap

Used during full-speed transactions, to set the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46  $\mu$ s.

### Register 24: USB Low-Speed Last Transaction to End of Frame Timing (USBLSEOF), offset 0x07E

**Host**

This 8-bit configuration register sets the minimum time gap that is to be allowed between the start of the last transaction and the EOF for low-speed transactions.

**Device**

USB Low-Speed Last Transaction to End of Frame Timing (USBLSEOF)

Base 0x4005.0000

Offset 0x07E

Type R/W, reset 0x72

Bit/Field	Name	Type	Reset	Description
7:0	LSEOFG	R/W	0x72	Low-Speed End-of-Frame Gap  Used during low-speed transactions, to set the gap between the last transaction and the End-of-Frame (EOF), in units of 1.067 $\mu$ s. The default corresponds to 121.6 $\mu$ s.

**Register 25: USB Transmit Functional Address Endpoint 0 (USBTXFUNCADDR0), offset 0x080**

**Register 26: USB Transmit Functional Address Endpoint 1 (USBTXFUNCADDR1), offset 0x088**

**Register 27: USB Transmit Functional Address Endpoint 2 (USBTXFUNCADDR2), offset 0x090**

**Register 28: USB Transmit Functional Address Endpoint 3 (USBTXFUNCADDR3), offset 0x098**

Host

USBTXFUNCADDRn is an 8-bit read/write register that records the address of the target function that is to be accessed through the associated endpoint (EPn). USBTXFUNCADDRn needs to be defined for each transmit endpoint that is used.

**Note:** USBTXFUNCADDR0 is used for both receive and transmit for endpoint 0.

USB Transmit Functional Address Endpoint 0 (USBTXFUNCADDR0)

Base 0x4005.0000  
 Offset 0x080  
 Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	ADDR	R/W	0x00	Device Address USB bus address for the target device.

**Register 29: USB Transmit Hub Address Endpoint 0 (USBTXHUBADDR0), offset 0x082**

**Register 30: USB Transmit Hub Address Endpoint 1 (USBTXHUBADDR1), offset 0x08A**

**Register 31: USB Transmit Hub Address Endpoint 2 (USBTXHUBADDR2), offset 0x092**

**Register 32: USB Transmit Hub Address Endpoint 3 (USBTXHUBADDR3), offset 0x09A**

Host

USBTXHUBADDR<sub>n</sub> is an 8-bit read/write register that, like USBTXHUBPORT<sub>n</sub>, only needs to be written when a USB device is connected to transmit endpoint EP<sub>n</sub> via a USB 2.0 hub. This register records the address of that USB 2.0 hub through which the target associated with the endpoint is accessed. This information, together with the hub port in USBTXHUBPORT<sub>n</sub>, allows the USB controller to support split transactions.

**Note:** USBTXHUBADDR0 is used for both receive and transmit for endpoint 0.

USB Transmit Hub Address Endpoint 0 (USBTXHUBADDR0)

Base 0x4005.0000

 Offset 0x08F  
 Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	PORT	R/W	0x00	Hub Port USB hub port number.

**Register 46: USB Maximum Transmit Data Endpoint 1 (USBTXMAXP1), offset 0x110**

**Register 47: USB Maximum Transmit Data Endpoint 2 (USBTXMAXP2), offset 0x120**

**Register 48: USB Maximum Transmit Data Endpoint 3 (USBTXMAXP3), offset 0x130**

**Host**

The **USBTXMAXPn** 16-bit register defines the maximum amount of data that can be transferred through the transmit endpoint in a single operation.

**Device**

Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operation.

The total amount of data represented by the value written to this register (specified payload  $\times$  *m*) must not exceed the FIFO size for the transmit endpoint, and should not exceed half the FIFO size if double-buffering is required.

If this register is changed after packets have been sent from the endpoint, the transmit endpoint FIFO should be completely flushed (using the `FLUSH` bit in **USBTXCSRL1n**) after writing the new value to this register.

**Note:** **USBTXMAXPn** must be set to an even number of bytes for proper interrupt generation in  $\mu$ DMA Mode 1.

USB Maximum Transmit Data Endpoint 1 (USBTXMAXP1)

Base 0x4005.0000  
Offset 0x110  
Type R/W, reset 0x0000

3	DATAEND	W1C	0	<p>Data End</p> <p>The CPU sets this bit:</p> <ul style="list-style-type: none"> <li>■ When setting TXRDY for the last data packet</li> <li>■ When clearing RXRDY after unloading the last data packet</li> <li>■ When setting TXRDY for a zero-length data packet</li> </ul> <p>It is cleared automatically.</p>

Bit/Field	Name	Type	Reset	Description
2	STALLED	R/W0C	0	Endpoint Stalled  This bit is set when a STALL handshake is transmitted. The CPU should clear this bit by writing a 0. This bit can only be cleared. Setting this bit does nothing.
1	TXRDY	R/W1S	0	Transmit Packet Ready  The CPU writes a 1 to this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is also generated at this point.
0	RXRDY	RO	0	Receive Packet Ready  This bit is set when a data packet has been received. An interrupt is generated when this bit is set. The CPU clears this bit by setting the RXRDYC bit.

## Register 50: USB Control and Status Endpoint 0 High (USBCSRH0), offset 0x103

Host

USBSR0H is an 8-bit register that provides control and status bits for endpoint 0.

Device

### Host Mode

#### USB Control and Status Endpoint 0 High (USBCSRH0)

Base 0x4005.0000  
Offset 0x103  
Type W1C, reset 0x00

	7	6	5	4	3	2	1	0
	reserved					DTWE	DT	FLUSH
Type	RO	RO	RO	RO	RO	W1S	R/W	W1C
Reset	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
7:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	DTWE	W1S	0	Data Toggle Write Enable  The CPU writes a 1 to this bit to enable the current state of the endpoint 0 data toggle to be written (see DT bit). This bit is automatically cleared once the new value is written.
1	DT	R/W	0	Data Toggle  When read, this bit indicates the current state of the endpoint 0 data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, this cannot be written.
0	FLUSH	W1C	0	Flush FIFO  The CPU writes a 1 to this bit to flush the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared.

**Important:** FLUSH should only be used when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted.

### Device Mode

#### USB Control and Status Endpoint 0 High (USBCSRH0)

**Important:** FLUSH should only be used when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted.

---

**Register 51: USB Receive Byte Count Endpoint 0 (USBCOUNT0), offset 0x108****Host**

**USBCOUNT0** is an 8-bit read-only register that indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while **RXRDY** is set.

**Device**

USB Receive Byte Count Endpoint 0 (USBCOUNT0)

Base 0x4005.0000

Offset 0x108

Type RO, reset 0x00

Bit/Field	Name	Type	Reset	Description
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	COUNT	RO	0x00	Count Count is a read-only value that indicates the number of received data bytes in the endpoint 0 FIFO.

### Register 52: USB Type Endpoint 0 (USBTYPE0), offset 0x10A

**Host**

This is an 8-bit register that should be written with the operating speed of the targeted device being communicated with using endpoint 0.

#### USB Type Endpoint 0 (USBTYPE0)

Base 0x4005.0000  
 Offset 0x10A  
 Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7:6	SPEED	R/W	0x00	Operating Speed  Operating speed of the target device. If selected, the target is assumed to have the same connection speed as the core.
				Value Description
				00 Reserved
				01 Reserved
				10 Full
				11 Low
5:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

**Register 53: USB NAK Limit (USBNAKLMT), offset 0x10B****Host**

**USBNAKLMT** is an 8-bit register that sets the number of frames after which endpoint 0 should time out on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their **USBTXINTERVALn** and **USBRXINTERVALn** registers.)

The number of frames selected is  $2^{(m-1)}$  (where  $m$  is the value set in the register, with valid values of 2–16). If the host receives NAK responses from the target for more frames than the number represented by the limit set in this register, the endpoint is halted.

**Note:** A value of 0 or 1 disables the NAK timeout function.

**USB NAK Limit (USBNAKLMT)**

Base 0x4005.0000  
Offset 0x10B  
Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7:5	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4:0	NAKLMT	R/W	0x00	EP0 NAK Limit Number of frames after receiving a stream of NAK responses.

**Register 54: USB Transmit Control and Status Endpoint 1 Low (USBTXCSRL1), offset 0x112**

**Register 60: USB Maximum Receive Data Endpoint 1 (USBRXMAXP1), offset 0x114**

**Register 61: USB Maximum Receive Data Endpoint 2 (USBRXMAXP2), offset 0x124**

**Register 62: USB Maximum Receive Data Endpoint 3 (USBRXMAXP3), offset 0x134**

**Host** The **USBRXMAXPn** 16-bit register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single operation.

**Device** Bits 10:0 define (in bytes) the maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes but is subject to the constraints placed by the *USB Specification* on packet sizes for bulk, interrupt and isochronous transfers in full-speed operations.

The total amount of data represented by the value written to this register (specified payload × *m*) must not exceed the FIFO size for the receive endpoint, and should not exceed half the FIFO size if double-buffering is required.

**Note:** **USBRXMAXPn** must be set to an even number of bytes for proper interrupt generation in  $\mu$ DMA Mode 1.

**Register 68: USB Receive Control and Status Endpoint 3 High (USBXCSRH3), offset 0x137**

Host

**USBXCSRHn** is an 8-bit register that provides additional control and status bits for transfers through the currently selected receive endpoint.

Device

**Host Mode**

**USB Receive Control and Status Endpoint 1 High (USBXCSRH1)**

Base 0x4005.0000  
 Offset 0x117  
 Type R/W, reset 0x00

	7	6	5	4	3	2	1	0
	AUTOCL	AUTORQ	DMAEN	PIDERR	DMAMOD	DTWE	DT	INCRX
Type	R/W	R/W	R/W	RO	R/W	RO	RO	R/W0C
Reset	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
7	AUTOCL	R/W	0	Auto Clear

If the CPU sets this bit, then the `RXRDY` bit is automatically cleared when a packet of `USBXMAXPn` bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, `RXRDY` must be cleared manually. Care must be taken when using  $\mu$ DMA to unload the receive FIFO as data is read from the receive FIFO in 4 byte chunks regardless of the `RxMaxP` bit.

**Note:** This bit should not be set for high-bandwidth isochronous endpoints.

6	AUTORQ	R/W	0	Auto Request
---	--------	-----	---	--------------

If the CPU sets this bit, the `ReqPkt` bit is automatically set when the `RXRDY` bit is cleared.

**Note:** This bit is automatically cleared when a short packet is received.

5	DMAEN	R/W	0	DMA Request Enable
---	-------	-----	---	--------------------

The CPU sets this bit to enable the  $\mu$ DMA request for the receive endpoint.

4	PIDERR	RO	0	PID Error
---	--------	----	---	-----------

For ISO transactions, the core sets this bit to indicate a PID error in the received packet. This bit is ignored in bulk or interrupt transactions.

Bit/Field	Name	Type	Reset	Description
3	DMAMOD	R/W	0	<p>DMA Request Mode</p> <p>The CPU sets this bit to select <math>\mu</math>DMA Request Mode 1 and clears it to select <math>\mu</math>DMA Request Mode 0.</p>
2	DTWE	RO	0	<p>Data Toggle Write Enable</p> <p>The CPU writes a 1 to this bit to enable the current state of the endpoint 0 data toggle to be written (see DT). This bit is automatically cleared once the new value is written.</p>
1	DT	RO	0	<p>Data Toggle</p> <p>When read, this bit indicates the current state of the endpoint 0 data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored.</p>
0	INCRX	R/W0C	0	<p>Incomplete Receive</p> <p>This bit is set in a high-bandwidth isochronous or interrupt transfer if the packet received is incomplete. It is cleared when RXRDY is cleared.</p> <p><b>Note:</b> If USB protocols are followed correctly, this bit should never be set. The bit becoming set indicates a failure of the associated peripheral device to behave correctly. (In anything other than isochronous transfer, this bit always returns 0.)</p>

## Device Mode

Host

**USBTXINTERVAL<sub>n</sub>** is an 8-bit register that, for interrupt and isochronous transfers, defines the polling interval for the currently selected transmit endpoint. For bulk endpoints, this register sets the number of frames after which the endpoint should time out on receiving a stream of NAK responses.

The **USBTXINTERVAL<sub>n</sub>** register value defines a number of frames, as follows:

Transfer Type	Speed	Valid values (m)	Interpretation
Interrupt	Low-Speed or Full-Speed	1 – 255	Polling interval is <i>m</i> frames.
Isochronous	Full-Speed	1 – 16	Polling interval is 2 <sup>(<i>m</i>-1)</sup> frames.
Bulk	Full-Speed	2 – 16	NAK Limit is 2 <sup>(<i>m</i>-1)</sup> frames. A value of 0 or 1 disables the NAK timeout function.

USB Host Transmit Interval Endpoint 1 (USBTXINTERVAL1)

### Register 81: USB Host Receive Polling Interval Endpoint 1 (USBRXINTERVAL1), offset 0x11D

### Register 82: USB Host Receive Polling Interval Endpoint 2 (USBRXINTERVAL2), offset 0x12D

### Register 83: USB Host Receive Polling Interval Endpoint 3 (USBRXINTERVAL3), offset 0x13D

Host

**USBRXINTERVAL1** is an 8-bit register that, for interrupt and isochronous transfers, defines the polling interval for the currently selected receive endpoint. For bulk endpoints, this register sets the number of frames after which the endpoint should time out on receiving a stream of NAK responses. The value that is set defines the number of frames, as follows:

Transfer Type	Speed	Valid Values ( <i>m</i> )	Interpretation
Interrupt	Low-Speed or Full-Speed	1 – 255	Polling interval is <i>m</i> frames.
Isochronous	Full-Speed	1 – 16	Polling interval is $2^{(m-1)}$ frames.
Bulk	Full-Speed	2 – 16	NAK Limit is $2^{(m-1)}$ frames.  <b>Note:</b> A value of 0 or 1 disables the NAK timeout function.

#### USB Host Receive Polling Interval Endpoint 1 (USBRXINTERVAL1)

Base 0x4005.0000  
Offset 0x11D  
Type R/W, reset 0x00

Bit/Field	Name	Type	Reset	Description
7:0	TXPOLL / NAKLMT	R/W	0x00	RX Polling / NAK Limit  Polling interval for interrupt/isochronous transfers; NAK limit for bulk transfers.

**Register 84: USB Request Packet Count in Block Transfer Endpoint 1 (USBRQPKTCOUNT1), offset 0x304**

**Register 85: USB Request Packet Count in Block Transfer Endpoint 2 (USBRQPKTCOUNT2), offset 0x308**

**Register 86: USB Request Packet Count in Block Transfer Endpoint 3 (USBRQPKTCOUNT3), offset 0x30C**

**Host**

This 16-bit read/write register is used in Host mode to specify the number of packets that are to be transferred in a block transfer of one or more bulk packets to receive endpoint *n*. The core uses the value recorded in this register to determine the number of requests to issue where the `AUTORQ` bit in the `USBRXCSRHn` register has been set. See “IN Transactions as a Host” on page 779.

**Note:** Multiple packets combined into a single bulk packet within the FIFO count as one packet.

USB Request Packet Count in Block Transfer Endpoint 1 (USBRQPKTCOUNT1)

Base 0x4005.0000  
 Offset 0x304  
 Type R/W, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:0	COUNT	R/W	0x00	Block Transfer Packet Count

Sets the number of packets of size `MaxP` that are to be transferred in a block transfer.

**Note:** This is only used in Host mode when `AUTORQ` is set. The bit has no effect in Device mode or when `AUTORQ` is not set.

## Register 87: USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS), offset 0x340

**Host**

**USBRXDPKTBUFDIS** is a 16-bit register that indicates which of the receive endpoints have disabled the double-packet buffer functionality (see the section called “Double-Packet Buffering” on page 775).

**Device**

**Note:** Bits relating to endpoints that have not been configured may be asserted by writing a 1 to their respective register; however the disable bit will have no observable effect.

### USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS)

### Register 89: USB External Power Control (USBEPIC), offset 0x400

Host

**USBEPIC** is instantiated in a USB unit in a wrapper around the USB controller/PHY IP. This 32-bit register specifies the function of the two-pin external power interface (`USB0EPEN` and `USB0PFLT`). The assertion of the power fault input may generate an automatic action, as controlled by the hardware configuration registers. The automatic action is necessary since the fault condition may require a response faster than one provided by firmware.

	The hardware has not generated an interrupt for a detected power fault condition.											
1	Interrupt											
	The hardware has generated an interrupt for a detected power fault condition.											

## Register 93: USB Device Resume Raw Interrupt Status (USBDRRIS), offset 0x410

Host

The **USBDRRIS** 32-bit register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

Device

USB Device Resume Raw Interrupt Status (USBDRRIS)

Base 0x4005.0000

Offset 0x410

Type RO, reset 0x0000.0000

	The hardware has generated an interrupt for a detected Resume.											

### Register 96: USB VBUS Droop Control (USBVDC), offset 0x430

OTG

Host

This 32-bit register enables a controlled masking of VBUS to compensate for any in-rush current by a device that is connected to the host controller. The in-rush current can cause VBUS to droop, causing the USB controller's behavior to be unexpected. The USB host controller allows VBUS to fall lower than the VBusValid level (4.5 V) but not below AValid (2.0 V) for 65 microseconds without signaling a `VBUSERR` interrupt in the controller. Without this, any glitch on VBUS would force the USB host controller to remove power from VBUS and then re-enumerate the device.

#### USB VBUS Droop Control (USBVDC)

Base 0x4005.0000  
 Offset 0x430  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
3:0	DMAA	R/W	0x1	DMA A Select Specifies the RX and TX mapping of the first USB endpoint on $\mu$ DMA channels 0 and 1 (primary assignment). Same bit definitions as the <code>DMAC</code> field.

## 21 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages, and provides a logical output that signals the comparison result.

**Note:** Not all comparators have the option to drive an output pin.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The Stellaris<sup>®</sup> Analog Comparators module has the following features:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of these voltages
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

## 21.1 Block Diagram

Figure 21-1. Analog Comparator Module Block Diagram

## 21.2 Functional Description

**Important:** It is recommended that the Digital-Input enable (the `GPIOEN` bit in the GPIO module) for the analog input pin be disabled to prevent excessive current draw from the I/O pads.

The comparator compares the  $V_{IN-}$  and  $V_{IN+}$  inputs to produce an output,  $V_{OUT}$ .

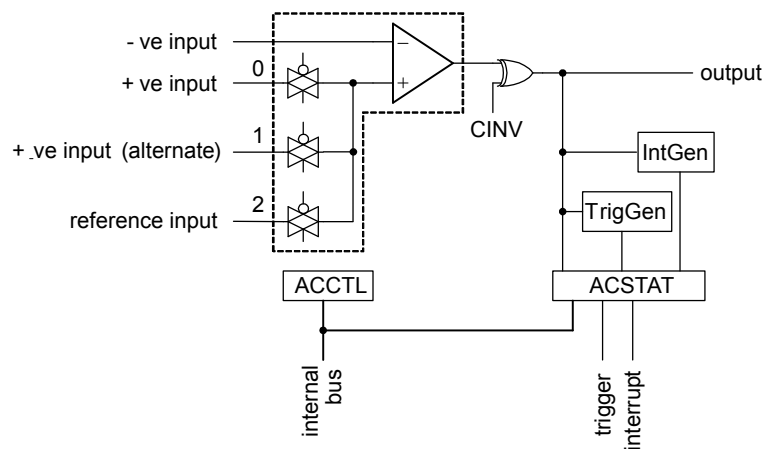

$$V_{IN-} < V_{IN+}, V_{OUT} = 1$$

$$V_{IN-} > V_{IN+}, V_{OUT} = 0$$

As shown in Figure 21-2 on page 873, the input source for  $V_{IN-}$  is an external input. In addition to an external input, input sources for  $V_{IN+}$  can be the +ve input of comparator 0 or an internal reference.

Figure 21-2. Structure of Comparator Unit

A comparator is configured through two status/control registers (**ACCTL** and **ACSTAT**). The internal reference is configured through one control register (**ACREFCTL**). Interrupt status and control is configured through three registers (**ACMIS**, **ACRIS**, and **ACINTEN**).

Typically, the comparator output is used internally to generate controller interrupts. It may also be used to drive an external pin or generate an analog-to-digital converter (ADC) trigger.

**Important:** The **ASRCP** bits in the **ACCTLn** register must be set before using the analog comparators.

### 21.2.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 21-3 on page 873. This is controlled by a single configuration register (**ACREFCTL**). Table 21-1 on page 873 shows the programming options to develop specific internal reference values, to compare an external voltage against a particular voltage generated internally ( $V_{IREF}$ ).

Figure 21-3. Comparator Internal Reference Structure

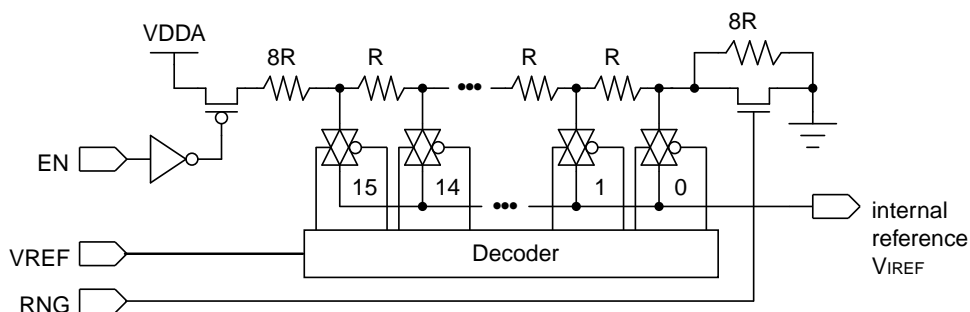

Table 21-1. Internal Reference Voltage and ACREFCTL Field Values

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value
EN Bit Value	RNG Bit Value	
EN=0	RNG=X	0 V (GND) for any value of VREF; however, it is recommended that RNG=1 and VREF=0 for the least noisy ground reference.

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value
EN Bit Value	RNG Bit Value	
EN=1	RNG=0	<p>Total resistance in ladder is 31 R.</p> $V_{IREF} = V_{DDA} \times \frac{R_{VREF}}{R_T}$ $V_{IREF} = V_{DDA} \times \frac{(VREF + 8)}{31}$ $V_{IREF} = 0.85 + 0.106 \times VREF$ <p>The range of internal reference in this mode is 0.85-2.448 V.</p>
	RNG=1	<p>Total resistance in ladder is 23 R.</p> $V_{IREF} = V_{DDA} \times \frac{R_{VREF}}{R_T}$ $V_{IREF} = V_{DDA} \times \frac{VREF}{23}$ $V_{IREF} = 0.143 \times VREF$ <p>The range of internal reference for this mode is 0-2.152 V.</p>

## 21.3 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator 0 clock by writing a value of 0x0010.0000 to the **RCGC1** register in the System Control module. See page 167.
2. In the GPIO module, enable the GPIO port/pin associated with C0- as a GPIO input.
3. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
4. Configure comparator 0 to use the internal voltage reference and to *not* invert the output by writing the **ACCTL0** register with the value of 0x0000.040C.
5. Delay for some time.
6. Read the comparator output value by reading the **ACSTAT0** register's **OVAL** value.

Change the level of the signal input on C0- to see the **OVAL** value change.

## 21.4 Register Map

Table 21-2 on page 875 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 167).

**Table 21-2. Analog Comparators Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	ACMIS	R/W1C	0x0000.0000	Analog Comparator Masked Interrupt Status	876
0x004	ACRIS	RO	0x0000.0000	Analog Comparator Raw Interrupt Status	877
0x008	ACINTEN	R/W	0x0000.0000	Analog Comparator Interrupt Enable	878
0x010	ACREFCTL	R/W	0x0000.0000	Analog Comparator Reference Voltage Control	879
0x020	ACSTAT0	RO	0x0000.0000	Analog Comparator Status 0	880
0x024	ACCTL0	R/W	0x0000.0000	Analog Comparator Control 0	881
0x040	ACSTAT1	RO	0x0000.0000	Analog Comparator Status 1	880
0x044	ACCTL1	R/W	0x0000.0000	Analog Comparator Control 1	881
0x060	ACSTAT2	RO	0x0000.0000	Analog Comparator Status 2	880
0x064	ACCTL2	R/W	0x0000.0000	Analog Comparator Control 2	881

## 21.5 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

## Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000

This register provides a summary of the interrupt status (masked) of the comparator.

### Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000

Offset 0x000

Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved													IN2	IN1	IN0	
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W1C	R/W1C	R/W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	IN2	R/W1C	0	Comparator 2 Masked Interrupt Status  Gives the masked interrupt state of this interrupt. Write 1 to this bit to clear the pending interrupt.
1	IN1	R/W1C	0	Comparator 1 Masked Interrupt Status  Gives the masked interrupt state of this interrupt. Write 1 to this bit to clear the pending interrupt.
0	IN0	R/W1C	0	Comparator 0 Masked Interrupt Status  Gives the masked interrupt state of this interrupt. Write 1 to this bit to clear the pending interrupt.

## Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004

This register provides a summary of the interrupt status (raw) of the comparator.

### Analog Comparator Raw Interrupt Status (ACRIS)

Base 0x4003.C000

Offset 0x004

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved													IN2	IN1	IN0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	IN2	RO	0	Comparator 2 Interrupt Status When set, indicates that an interrupt has been generated by comparator 2.
1	IN1	RO	0	Comparator 1 Interrupt Status When set, indicates that an interrupt has been generated by comparator 1.
0	IN0	RO	0	Comparator 0 Interrupt Status When set, indicates that an interrupt has been generated by comparator 0.

### Register 3: Analog Comparator Interrupt Enable (ACINTEN), offset 0x008

This register provides the interrupt enable for the comparator.

#### Analog Comparator Interrupt Enable (ACINTEN)

Base 0x4003.C000  
 Offset 0x008  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	IN2	R/W	0	Comparator 2 Interrupt Enable When set, enables the controller interrupt from the comparator 2 output
1	IN1	R/W	0	Comparator 1 Interrupt Enable When set, enables the controller interrupt from the comparator 1 output.
0	IN0	R/W	0	Comparator 0 Interrupt Enable When set, enables the controller interrupt from the comparator 0 output.

## Register 4: Analog Comparator Reference Voltage Control (ACREFCTL), offset 0x010

This register specifies whether the resistor ladder is powered on as well as the range and tap.

### Analog Comparator Reference Voltage Control (ACREFCTL)

Base 0x4003.C000

Offset 0x010

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved						EN	RNG	reserved				VREF			
Type	RO	RO	RO	RO	RO	RO	R/W	R/W	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	EN	R/W	0	Resistor Ladder Enable  The <b>EN</b> bit specifies whether the resistor ladder is powered on. If 0, the resistor ladder is unpowered. If 1, the resistor ladder is connected to the analog $V_{DD}$ .  This bit is reset to 0 so that the internal reference consumes the least amount of power if not used and programmed.
8	RNG	R/W	0	Resistor Ladder Range  The <b>RNG</b> bit specifies the range of the resistor ladder. If 0, the resistor ladder has a total resistance of 31 R. If 1, the resistor ladder has a total resistance of 23 R.
7:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	VREF	R/W	0x00	Resistor Ladder Voltage Ref  The <b>VREF</b> bit field specifies the resistor ladder tap that is passed through an analog multiplexer. The voltage corresponding to the tap position is the internal reference voltage available for comparison. See Table 21-1 on page 873 for some output reference voltage examples.

**Register 5: Analog Comparator Status 0 (ACSTAT0), offset 0x020**

**Register 6: Analog Comparator Status 1 (ACSTAT1), offset 0x040**

**Register 7: Analog Comparator Status 2 (ACSTAT2), offset 0x060**

These registers specify the current output value of the comparator.

Analog Comparator Status 0 (ACSTAT0)

Base 0x4003.C000  
 Offset 0x020  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	OVAL	RO	0	Comparator Output Value  The OVAL bit specifies the current output value of the comparator.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

**Register 8: Analog Comparator Control 0 (ACCTL0), offset 0x024****Register 9: Analog Comparator Control 1 (ACCTL1), offset 0x044****Register 10: Analog Comparator Control 2 (ACCTL2), offset 0x064**

These registers configure the comparator's input and output.

## Analog Comparator Control 0 (ACCTL0)

Base 0x4003.C000

Offset 0x024

Type R/W, reset 0x0000.0000

## 22 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The Stellaris<sup>®</sup> PWM module consists of four PWM generator blocks and a control block. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that can either be independent signals (other than being based on the same timer and therefore having the same frequency) or a single pair of complementary signals with dead-band delays inserted. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins.

The Stellaris<sup>®</sup> PWM module provides a great deal of flexibility. It can generate simple PWM signals, such as those required by a simple charge pump. It can also generate paired PWM signals with dead-band delays, such as those required by a half-H bridge driver. Three generator blocks can also generate the full six channels of gate controls required by a 3-phase inverter bridge.

Each Stellaris<sup>®</sup> PWM module has the following features:

- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified
- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended fault capabilities with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

## 22.1 Block Diagram

Figure 22-1 on page 884 provides the Stellaris<sup>®</sup> PWM module unit diagram and Figure 22-2 on page 885 provides a more detailed diagram of a Stellaris<sup>®</sup> PWM generator. The LM3S9792 controller contains four generator blocks (PWM0, PWM1, PWM2, and PWM3) and generates eight independent PWM signals or four paired PWM signals with dead-band delays inserted.

**Figure 22-1. PWM Unit Diagram**

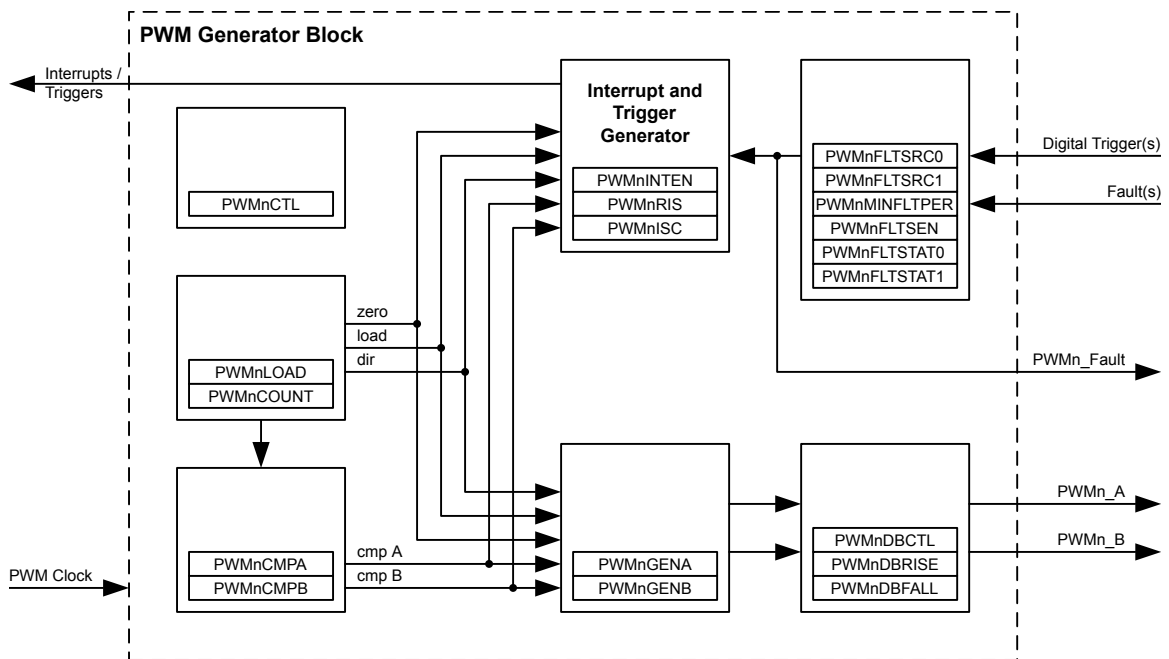

Figure 22-2. PWM Module Block Diagram

## 22.2 Functional Description

### 22.2.1 PWM Timer

The timer in each PWM generator runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse.

### 22.2.2 PWM Comparators

There are two comparators in each PWM generator that monitor the value of the counter; when either match the counter, they output a single-clock-cycle-width High pulse. When in Count-Up/Down mode, these comparators match both when counting up and when counting down; they are therefore qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 22-3 on page 886 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 22-4 on page 886 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode.

**Figure 22-3. PWM Count-Down Mode**

**Figure 22-4. PWM Count-Up/Down Mode**

### 22.2.3 PWM Signal Generator

The PWM generator takes these pulses (qualified by the direction signal), and generates two PWM signals. In Count-Down mode, there are four events that can affect the PWM signal: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect the PWM signal: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal,  $PWMA$ , is generated based only on the match A event, and the second signal,  $PWMB$ , is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 22-5 on page 887 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles.

**Figure 22-5. PWM Generation Example In Count-Up/Down Mode**

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the `PWMA` signal, and changing the value of comparator B changes the duty cycle of the `PWMB` signal.

#### 22.2.4 Dead-Band Generator

The two PWM signals produced by the PWM generator are passed to the dead-band generator. If disabled, the PWM signals simply pass through unmodified. If enabled, the second PWM signal is lost and two PWM signals are generated based on the first PWM signal. The first output PWM signal is the input signal with the rising edge delayed by a programmable amount. The second output PWM signal is the inversion of the input signal with a programmable delay added between the falling edge of the input signal and the rising edge of this new signal.

This is therefore a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 22-6 on page 887 shows the effect of the dead-band generator on an input PWM signal.

**Figure 22-6. PWM Dead-Band Generator**

#### 22.2.5 Interrupt/ADC-Trigger Selector

The PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position within the PWM signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

## 22.2.6 Synchronization Methods

The PWM unit provides four PWM generators providing eight PWM outputs that may be used in a wide variety of applications. Generally speaking, this falls into combinations of two categories of operation:

- **Unsynchronized.** The PWM generator and its two output signals are used by itself, independent of other PWM generators.
- **Synchronized.** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base.

If multiple PWM generators are configured with the same counter load value, this can be used to guarantee that they also have the same count value (this does imply that the PWM generators must be configured before they are synchronized). With this, more than two PWM signals can be produced with a known relationship between the edges of those signals since the counters always have the same values. Other states in the unit provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM unit generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the `Sync` bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary `Sync` bits in one access. For example, setting the `Sync0` and `Sync1` bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additionally, the state of a PWM unit is affected by writing to the registers of the PWM unit and the PWM units' generators, which has an effect on the synchronization between multiple PWM generators. Depending on the register accessed, the register state is updated in one of the following three ways:

- **Immediately.** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized.** The write value does not affect the logic until the counter reaches the value zero. In this case, the effect of the write is deferred until the end of the PWM cycle (when the counter reaches zero). By waiting for the counter to reach zero, a guaranteed behavior is defined, and overly short or overly long output PWM pulses are prevented.
- **Globally Synchronized.** The write value does not affect the logic until two sequential events have occurred: (1) the global synchronization bit applicable to the generator is set, and (2) the counter reaches zero. In this case, the effect of the write is deferred until the end of the PWM cycle (when the counter reaches zero) following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of the **PWMnCTL** register `Update` bit value:

- Generator Registers: **PWMnLOAD**, **PWMnCMPA**, and **PWMnCMPB**

The following registers are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect. The default update mode is immediate.

- Module-Level Register: **PWMENABLE**
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL**.

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization, and therefore, do not need synchronous update functionality.

### 22.2.7 Fault Conditions

A fault condition is one in which the controller must be signaled to stop normal PWM function and then sets the outputs to a safe state. There are two basic situations where this becomes necessary:

- The controller is stalled and cannot perform the necessary computation in the time required for motion control
- An external error or event is detected, such as an error

The PWM unit can use the following inputs to generate a fault condition, including:

- **FAULT<sub>n</sub>** pin assertion
- A stall of the controller generated by the debugger
- The trigger of an ADC digital comparator

Fault conditions are calculated on a per-PWM generator basis. Each PWM generator configures the necessary conditions to indicate a fault condition exists. This method allows the development of applications with dependent and independent control.

Each PWM generator's mode control, including fault condition handling, is provided in the **PWMnCTL** register. This register determines whether a single **FAULT<sub>0</sub>** input is used (as previous Stellaris<sup>®</sup> products support) or whether all **FAULT<sub>n</sub>** input signals may be used to generate a fault condition. This register allows the fault condition duration to last as long as the external condition lasts, or it may specify that the external condition be latched and the fault condition (and its effects) last until cleared by software. Finally, this register also enables a counter that may be used to extend the period of a fault condition for external events to assure that the duration is a minimum length. The minimum fault period count is specified in the **PWMnMINFLTPER** register.

These PWM generator registers provide status, control, and configure the fault condition in each PWM generator: **PWMnFLTSRC0**, **PWMnFLTSRC1**, **PWMnFLTSTAT0**, **PWMnFLTSTAT1**, and **PWMnFLTSEN**.

There are up to four **FAULT** input pins (**FAULT<sub>0</sub>**-**FAULT<sub>3</sub>**). These pins may be used with circuits that generate an active High or active Low signal to indicate an error condition. Each of the **FAULT<sub>n</sub>** pins may be individually programmed for this logic sense using the **PWMnFLTSEN** register.

The **PWMnFLTSRC0** and **PWMnFLTSRC1** registers define the contribution of the external fault sources. Using these registers, individual or groups of **FAULT<sub>n</sub>** signals are ORed together to specify the external fault generating conditions.

Status regarding the specific fault cause is provided in **PWMnFLTSTAT0** and **PWMnFLTSTAT1**.

PWM generator fault conditions may be promoted to a controller interrupt using the **PWMINTEN** register.

During fault conditions, the PWM output signals usually require being driven to safe values so that external equipment may be safely controlled. To facilitate this, the **PWMFAULT** register is used to determine if the generated signal continues to be passed driven, or a specific fault condition encoding is driven on the PWM output, as specified in the **PWMFAULTVAL** register.

### 22.2.8 Output Control Block

With each PWM generator block producing two raw PWM signals, the output control block takes care of the final conditioning of the PWM signals before they go to the pins. Via a single register, the set of PWM signals that are actually enabled to the pins can be modified; this can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). Similarly, fault control can disable any of the PWM signals as well. A final inversion can be applied to any of the PWM signals, making them active Low instead of the default active High.

## 22.3 Initialization and Configuration

The following example shows how to initialize the PWM Generator 0 with a 25-KHz frequency, and with a 25% duty cycle on the `PWM0` pin and a 75% duty cycle on the `PWM1` pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by writing a value of `0x0010.0000` to the **RCGC0** register in the System Control module. See page 158.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module. See page 179.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register.
4. Configure the **Run-Mode Clock Configuration (RCC)** register in the System Control module to use the PWM divide (`USEPWMDIV`) and set the divider (`PWMDIV`) to divide by 2 (000).
5. Configure the PWM generator for countdown mode with immediate updates to the parameters.
  - Write the **PWM0CTL** register with a value of `0x0000.0000`.
  - Write the **PWM0GENA** register with a value of `0x0000.008C`.
  - Write the **PWM0GENB** register with a value of `0x0000.080C`.
6. Set the period. For a 25-KHz frequency, the period =  $1/25,000$ , or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. This translates to 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the `Load` field in the **PWM0LOAD** register to the requested period minus one.
  - Write the **PWM0LOAD** register with a value of `0x0000.018F`.
7. Set the pulse width of the `PWM0` pin for a 25% duty cycle.
  - Write the **PWM0CMPA** register with a value of `0x0000.012B`.
8. Set the pulse width of the `PWM1` pin for a 75% duty cycle.
  - Write the **PWM0CMPB** register with a value of `0x0000.0063`.

9. Start the timers in PWM generator 0.
  - Write the **PWM0CTL** register with a value of 0x0000.0001.
10. Enable PWM outputs.
  - Write the **PWMENABLE** register with a value of 0x0000.0003.

## 22.4 Register Map

Table 22-1 on page 891 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM base address of 0x4002.8000. Note that the PWM module clock must be enabled before the registers can be programmed (see page 158).

**Table 22-1. PWM Register Map**

Offset	Name	Type	Reset	Description	See page
0x000	PWM0CTL	R/W	0x0000.0000	PWM Master Control	894
0x004	PWMSYNC	R/W	0x0000.0000	PWM Time Base Sync	895

## 22.5 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

### Register 1: PWM Master Control (PWMCTL), offset 0x000

This register provides master control over the PWM generation blocks.

#### PWM Master Control (PWMCTL)

Base 0x4002.8000  
 Offset 0x000  
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved												GlobalSync3	GlobalSync2	GlobalSync1	GlobalSync0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	GlobalSync3	R/W	0	Update PWM Generator 3 Same as GlobalSync0 but for PWM generator 3.
2	GlobalSync2	R/W	0	Update PWM Generator 2 Same as GlobalSync0 but for PWM generator 2.
1	GlobalSync1	R/W	0	Update PWM Generator 1 Same as GlobalSync0 but for PWM generator 1.
0	GlobalSync0	R/W	0	Update PWM Generator 0 Setting this bit causes any queued update to a load or comparator register in PWM generator 0 to be applied the next time the corresponding counter becomes zero. This bit automatically clears when the updates have completed; it cannot be cleared by software.

## Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Writing a bit in this register to 1 causes the specified counter to reset back to 0; writing multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

### PWM Time Base Sync (PWMSYNC)

Base 0x4002.8000  
Offset 0x004  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved												Sync3	Sync2	Sync1	Sync0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	Sync3	R/W	0	Reset Generator 3 Counter Performs a reset of the PWM generator 3 counter.
2	Sync2	R/W	0	Reset Generator 2 Counter Performs a reset of the PWM generator 2 counter.
1	Sync1	R/W	0	Reset Generator 1 Counter Performs a reset of the PWM generator 1 counter.
0	Sync0	R/W	0	Reset Generator 0 Counter Performs a reset of the PWM generator 0 counter.

### Register 3: PWM Output Enable (PWMENABLE), offset 0x008

This register provides a master control of which generated PWM signals are output to device pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding PWM signal is passed through to the output stage, which is controlled by the **PWMINVERT** register. When bits are not set, the PWM signal is replaced by a zero value which is also passed to the output stage.

#### PWM Output Enable (PWMENABLE)

Base 0x4002.8000  
 Offset 0x008  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	PWM7En	R/W	0	PWM7 Output Enable When set, allows the generated PWM7 signal to be passed to the device pin.
6	PWM6En	R/W	0	PWM6 Output Enable When set, allows the generated PWM6 signal to be passed to the device pin.
5	PWM5En	R/W	0	PWM5 Output Enable When set, allows the generated PWM5 signal to be passed to the device pin.
4	PWM4En	R/W	0	PWM4 Output Enable When set, allows the generated PWM4 signal to be passed to the device pin.
3	PWM3En	R/W	0	PWM3 Output Enable When set, allows the generated PWM3 signal to be passed to the device pin.
2	PWM2En	R/W	0	PWM2 Output Enable When set, allows the generated PWM2 signal to be passed to the device pin.

Bit/Field	Name	Type	Reset	Description
1	PWM1En	R/W	0	PWM1 Output Enable When set, allows the generated PWM1 signal to be passed to the device pin.
0	PWM0En	R/W	0	PWM0 Output Enable When set, allows the generated PWM0 signal to be passed to the device pin.

### Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C

This register provides a master control of the polarity of the PWM signals on the device pins. The PWM signals generated by the PWM generator are active High; they can optionally be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive channels maintain the correct polarity.

#### PWM Output Inversion (PWMINVERT)

Base 0x4002.8000  
 Offset 0x00C  
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved								PWM7Inv	PWM6Inv	PWM5Inv	PWM4Inv	PWM3Inv	PWM2Inv	PWM1Inv	PWM0Inv
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	PWM7Inv	R/W	0	Invert PWM7 Signal When set, the generated PWM7 signal is inverted.
6	PWM6Inv	R/W	0	Invert PWM6 Signal When set, the generated PWM6 signal is inverted.
5	PWM5Inv	R/W	0	Invert PWM5 Signal When set, the generated PWM5 signal is inverted.
4	PWM4Inv	R/W	0	Invert PWM4 Signal When set, the generated PWM4 signal is inverted.
3	PWM3Inv	R/W	0	Invert PWM3 Signal When set, the generated PWM3 signal is inverted.
2	PWM2Inv	R/W	0	Invert PWM2 Signal When set, the generated PWM2 signal is inverted.
1	PWM1Inv	R/W	0	Invert PWM1 Signal When set, the generated PWM1 signal is inverted.
0	PWM0Inv	R/W	0	Invert PWM0 Signal When set, the generated PWM0 signal is inverted.

## Register 5: PWM Output Fault (PWMFAULT), offset 0x010

This register controls the behavior of the PWM outputs in the presence of fault conditions. Both the fault inputs and debug events are considered fault conditions. On a fault condition, each PWM signal can be passed through unmodified or driven to a specified value. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the PWM signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

### PWM Output Fault (PWMFAULT)

Base 0x4002.8000  
Offset 0x010  
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved								Fault7	Fault6	Fault5	Fault4	Fault3	Fault2	Fault1	Fault0
Type	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	Fault7	R/W	0	PWM7 Fault  When set, the $PWM7$ output signal is driven to a specified value on a fault condition.

0	Fault0	R/W	0	PWM0 Fault When set, the PWM0 output signal is driven to a specified value on a fault condition.

## Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generators.

### PWM Interrupt Enable (PWMINTEN)

1	IntPWM1	R/W	0	PWM1 Interrupt Enable  When set, an interrupt occurs when the PWM generator 1 block asserts an interrupt.

Bit/Field	Name	Type	Reset	Description
0	IntPWM0	R/W	0	PWM0 Interrupt Enable When set, an interrupt occurs when the PWM generator 0 block asserts an interrupt.

## Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller. The fault interrupt is latched on detection; it must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register (see page 905). The PWM generator interrupts simply reflect the status of the PWM generators; they are cleared via the interrupt status register in the PWM generator blocks. Bits set to 1 indicate the events that are active; zero bits indicate that the event in question is not active.

### PWM Raw Interrupt Status (PWMRIS)

3	IntPWM3	RO	0	PWM3 Interrupt Asserted Indicates that the PWM generator 3 block is asserting its interrupt.
2	IntPWM2	RO	0	PWM2 Interrupt Asserted Indicates that the PWM generator 2 block is asserting its interrupt.
1	IntPWM1	RO	0	PWM1 Interrupt Asserted Indicates that the PWM generator 1 block is asserting its interrupt.

Bit/Field	Name	Type	Reset	Description
0	IntPWM0	RO	0	PWM0 Interrupt Asserted Indicates that the PWM generator 0 block is asserting its interrupt.

### Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the individual PWM generator blocks. A bit set to 1 indicates that the corresponding generator block is asserting an interrupt. The individual interrupt status registers in each block must be consulted to determine the reason for the interrupt, and used to clear the interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status.

**Register 11: PWM0 Control (PWM0CTL), offset 0x040**

**Register 12: PWM1 Control (PWM1CTL), offset 0x080**

**Register 13: PWM2 Control (PWM2CTL), offset 0x0C0**

**Register 14: PWM3 Control (PWM3CTL), offset 0x100**

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the PWM0 and PWM1 outputs, the PWM1 block produces the PWM2 and PWM3 outputs, the PWM2 block produces the PWM4 and PWM5 outputs, and the PWM3 block produces the PWM6 and PWM7 outputs.

Bit/Field	Name	Type	Reset	Description
31:19	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
18	LATCH	R/W	0	<p>Latch Fault Input</p> <p>This bit controls the behavior of the fault condition in a PWM generator.</p> <p>The fault condition may be latched and internally asserted because the fault condition logic includes the generator's <code>IntFaultn</code> bit (of the <b>PWMISC</b> register) enabled by the <code>LATCH</code> bit.</p> <p>Therefore, if the <b>PWMINTEN</b> <code>IntFaultn</code> bit is set, a fault condition sets the <b>PWMISC</b> <code>IntFaultn</code> bit (generating an interrupt) and the fault condition is extended in the generator logic until software clears the <b>PWMISC</b> <code>IntFaultn</code> bit.</p> <p>Value Description</p> <p>0 Fault Condition Not Latched</p> <p>A fault condition is in effect for as long as the generating source is asserting.</p> <p>1 Fault Condition Latched</p> <p>A fault condition is set as the result of the assertion of the faulting source and is held (latched) while the <b>PWMISC</b> <code>IntFaultn</code> bit is set. Clearing the <code>IntFaultn</code> bit clears the fault condition.</p>
17	MINFLTPER	R/W	0	<p>Minimum Fault Period</p> <p>This bit specifies that the PWM generator enables a one-shot counter to provide a minimum fault condition period.</p> <p>The timer begins counting on the rising edge of the fault condition to extend the condition for a minimum duration of the count value. The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the <code>MINFLTPER</code> bit is set. If a detected fault is in the process of being extended when the <code>MINFLTPER</code> bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the <b>PWMnMINFLTPER</b> register <code>MFP</code> field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is <math>PWMClock * (MFP \text{ value} + 1)</math> or <math>PWMClock * (MFP \text{ value} + 2)</math>.</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the <code>FLTSRC</code> field.</p> <p>Value Description</p> <p>0 Fault Condition Period Not Extended</p> <p>The <code>FAULT</code> input deassertion is unaffected.</p> <p>1 Fault Condition Period Extended</p> <p>The <b>PWMnMINFLTPER</b> one-shot counter is active and extends the period of the fault condition to a minimum period.</p>

When set, the counter counts up from 0 to the load value, back down to 0, and then repeats (Count-Up/Down mode).</p>										
0	Enable	R/W	0	<p>PWM Block Enable</p> <p>Master enable for the PWM generation block. When not set, the entire block is disabled and not clocked. When set, the block is enabled and produces PWM signals.</p>										

**Register 15: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044**

**Register 16: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084**

**Register 17: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4**

**Register 18: PWM3 Interrupt and Trigger Enable (PWM3INTEN), offset 0x104**

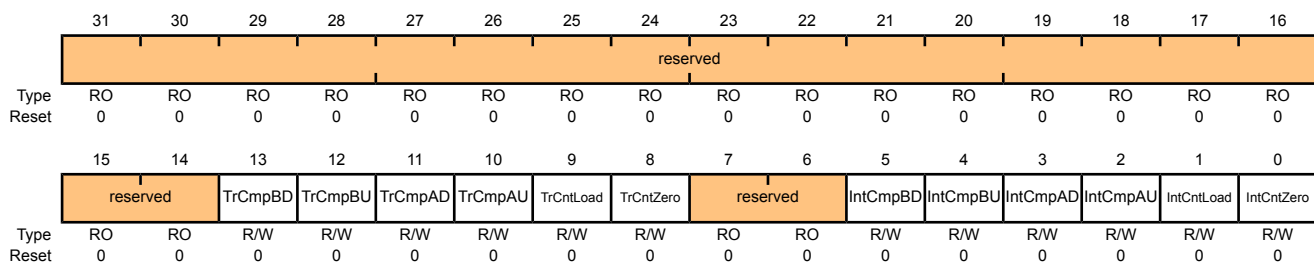

These registers control the interrupt and ADC trigger generation capabilities of the PWM generators (**PWM0INTEN** controls the PWM generator 0 block, and so on). The events that can cause an interrupt or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the comparator A register while counting up
- The counter being equal to the comparator A register while counting down
- The counter being equal to the comparator B register while counting up
- The counter being equal to the comparator B register while counting down

Any combination of these events can generate either an interrupt, or an ADC trigger; though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified.

**PWM0 Interrupt and Trigger Enable (PWM0INTEN)**

**Register 23: PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C**

**Register 24: PWM1 Interrupt Status and Clear (PWM1ISC), offset 0x08C**

**Register 25: PWM2 Interrupt Status and Clear (PWM2ISC), offset 0x0CC**

**Register 26: PWM3 Interrupt Status and Clear (PWM3ISC), offset 0x10C**

These registers provide the current set of interrupt sources that are asserted to the controller (**PWM0ISC** controls the PWM generator 0 block, and so on). Bits set to 1 indicate the latched events that have occurred; bits set to 0 indicate that the event in question has not occurred. These are R/W1C registers; writing a 1 to a bit position clears the corresponding interrupt reason.

PWM0 Interrupt Status and Clear (PWM0ISC)

Base 0x4002.8000  
 Offset 0x04C  
 Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	IntCmpBD	R/W1C	0	Comparator B Down Interrupt  Indicates that the counter has matched the comparator B value while counting down.
4	IntCmpBU	R/W1C	0	Comparator B Up Interrupt  Indicates that the counter has matched the comparator B value while counting up.
3	IntCmpAD	R/W1C	0	Comparator A Down Interrupt  Indicates that the counter has matched the comparator A value while counting down.
2	IntCmpAU	R/W1C	0	Comparator A Up Interrupt  Indicates that the counter has matched the comparator A value while counting up.
1	IntCntLoad	R/W1C	0	Counter=Load Interrupt  Indicates that the counter has matched the <b>PWMnLOAD</b> register.
0	IntCntZero	R/W1C	0	Counter=0 Interrupt  Indicates that the counter has matched 0.

**Register 27: PWM0 Load (PWM0LOAD), offset 0x050**

**Register 28: PWM1 Load (PWM1LOAD), offset 0x090**

**Register 29: PWM2 Load (PWM2LOAD), offset 0x0D0**

**Register 30: PWM3 Load (PWM3LOAD), offset 0x110**

These registers contain the load value for the PWM counter (**PWM0LOAD** controls the PWM generator 0 block, and so on). Based on the counter mode, either this value is loaded into the counter after it reaches zero, or it is the limit of up-counting after which the counter decrements back to zero.

If the Load Value Update mode is immediate, this value is used the next time the counter reaches zero; if the mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 894). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

PWM0 Load (PWM0LOAD)

Base 0x4002.8000  
 Offset 0x050  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	Load	R/W	0	Counter Load Value The counter load value.

**Register 31: PWM0 Counter (PWM0COUNT), offset 0x054**

**Register 32: PWM1 Counter (PWM1COUNT), offset 0x094**

**Register 33: PWM2 Counter (PWM2COUNT), offset 0x0D4**

**Register 34: PWM3 Counter (PWM3COUNT), offset 0x114**

These registers contain the current value of the PWM counter. When this value matches the load register, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers, see page 923 and page 926) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register, see page 915). A pulse with the same capabilities is generated when this value is zero.

PWM0 Counter (PWM0COUNT)

Base 0x4002.8000  
 Offset 0x054  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	Count	RO	0x00	Counter Value The current value of the counter.

**Register 35: PWM0 Compare A (PWM0CMPA), offset 0x058****Register 36: PWM1 Compare A (PWM1CMPA), offset 0x098****Register 37: PWM2 Compare A (PWM2CMPA), offset 0x0D8****Register 38: PWM3 Compare A (PWM3CMPA), offset 0x118**

These registers contain a value to be compared against the counter (**PWM0CMPA** controls the PWM generator 0 block, and so on). When this value matches the counter, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register (see page 919), then no pulse is ever output.

If the comparator A update mode is immediate (based on the **CompAUpd** bit in the **PWMnCTL** register), this 16-bit **CompA** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 894). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

## PWM0 Compare A (PWM0CMPA)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CompA	R/W	0x00	Comparator A Value The value to be compared against the counter.

**Register 39: PWM0 Compare B (PWM0CMPB), offset 0x05C**

**Register 40: PWM1 Compare B (PWM1CMPB), offset 0x09C**

**Register 41: PWM2 Compare B (PWM2CMPB), offset 0x0DC**

**Register 42: PWM3 Compare B (PWM3CMPB), offset 0x11C**

These registers contain a value to be compared against the counter (**PWM0CMPB** controls the PWM generator 0 block, and so on). When this value matches the counter, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register, no pulse is ever output.

If the comparator B update mode is immediate (based on the **CompBUpd** bit in the **PWMnCTL** register), this 16-bit **CompB** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 894). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWM0 Compare B (PWM0CMPB)

Base 0x4002.8000  
 Offset 0x05C  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CompB	R/W	0x00	Comparator B Value The value to be compared against the counter.

**Register 43: PWM0 Generator A Control (PWM0GENA), offset 0x060**

**Register 44: PWM1 Generator A Control (PWM1GENA), offset 0x0A0**

**Register 45: PWM2 Generator A Control (PWM2GENA), offset 0x0E0**

**Register 46: PWM3 Generator A Control (PWM3GENA), offset 0x120**

These registers control the generation of the  $PWM_nA$  signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENA** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the PWM signal that is produced.

The **PWM0GENA** register controls generation of the  $PWM0A$  signal; **PWM1GENA**, the  $PWM1A$  signal; **PWM2GENA**, the  $PWM2A$  signal; and **PWM3GENA**, the  $PWM3A$  signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the  $GenAUpd$  field encoding in the **PWMnCTL** register), this 16-bit  $GenAUpd$  value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 894). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 47: PWM0 Generator B Control (PWM0GENB), offset 0x064**

**Register 48: PWM1 Generator B Control (PWM1GENB), offset 0x0A4**

**Register 49: PWM2 Generator B Control (PWM2GENB), offset 0x0E4**

**Register 50: PWM3 Generator B Control (PWM3GENB), offset 0x124**

These registers control the generation of the  $PWM_nB$  signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENB** controls the PWM generator 0 block, and so on). When the counter is running in Down mode, only four of these events occur; when running in Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the PWM signal that is produced.

The **PWM0GENB** register controls generation of the  $PWM0B$  signal; **PWM1GENB**, the  $PWM1B$  signal; **PWM2GENB**, the  $PWM2B$  signal; and **PWM3GENB**, the  $PWM3B$  signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

If the Generator B update mode is immediate (based on the  $GenBU_{pd}$  field encoding in the **PWMnCTL** register), this 16-bit  $GenBU_{pd}$  value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 894). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWM0 Generator B Control (PWM0GENB)**

**Register 51: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068**

**Register 52: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8**

**Register 53: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8**

**Register 54: PWM3 Dead-Band Control (PWM3DBCTL), offset 0x128**

The **PWM0DBCTL** register controls the dead-band generator, which produces the **PWM0** and **PWM1** signals based on the **PWM0A** and **PWM0B** signals. When disabled, the **PWM0A** signal passes through to the **PWM0** signal and the **PWM0B** signal passes through to the **PWM1** signal. When enabled and inverting the resulting waveform, the **PWM0B** signal is ignored; the **PWM0** signal is generated by delaying the rising edge(s) of the **PWM0A** signal by the value in the **PWM0DBRISE** register (see page 930), and the **PWM1** signal is generated by delaying the falling edge(s) of the **PWM0A** signal by the value in the **PWM0DBFALL** register (see page 931). In a similar manner, **PWM2** and **PWM3** are produced from the **PWM1A** and **PWM1B** signals, **PWM4** and **PWM5** are produced from the **PWM2A** and **PWM2B** signals, and **PWM6** and **PWM7** are produced from the **PWM3A** and **PWM3B** signals.

If the Dead-Band Control mode is immediate (based on the **DBCtlUpd** field encoding in the **PWMnCTL** register), this 16-bit **DBCtlUpd** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 894). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWM0 Dead-Band Control (PWM0DBCTL)**

31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	Enable	R/W	0	Dead-Band Generator Enable  When set, the dead-band generator inserts dead bands into the output signals; when clear, it simply passes the PWM signals through.

**Register 55: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C**

**Register 56: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC**

**Register 57: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC**

**Register 58: PWM3 Dead-Band Rising-Edge Delay (PWM3DBRISE), offset 0x12C**

The **PWM0DBRISE** register contains the number of clock ticks to delay the rising edge of the **PWM0A** signal when generating the **PWM0** signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, the **PWM0DBRISE** register is ignored. If the value of this register is larger than the width of a High pulse on the input PWM signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the input High time always exceeds the rising-edge delay. In a similar manner, **PWM2** is generated from **PWM1A** with its rising edge delayed; **PWM4** is produced from **PWM2A** with its rising edge delayed; and **PWM6** is produced from **PWM3A** with its rising edge delayed.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the **DBRiseUpd** field encoding in the **PWMnCTL** register), this 16-bit **DBRiseUpd** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 894). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	RiseDelay	R/W	0	Dead-Band Rise Delay  The number of clock ticks to delay the rising edge.

**Register 59: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070**

**Register 60: PWM1 Dead-Band Falling-Edge-Delay (PWM1DBFALL), offset 0x0B0**

**Register 61: PWM2 Dead-Band Falling-Edge-Delay (PWM2DBFALL), offset 0x0F0**

**Register 62: PWM3 Dead-Band Falling-Edge-Delay (PWM3DBFALL), offset 0x130**

The **PWM0DBFALL** register contains the number of clock ticks to delay the falling edge of the **PWM0A** signal when generating the **PWM1** signal. If the dead-band generator is disabled, this register is ignored. If the value of this register is larger than the width of a Low pulse on the input **PWM** signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the input Low time always exceeds the falling-edge delay. In a similar manner, **PWM3** is generated from **PWM1A** with its falling edge delayed, **PWM5** is produced from **PWM2A** with its falling edge delayed, and **PWM7** is produced from **PWM3A** with its falling edge delayed.

If the Dead-Band Falling-Edge-Delay mode is immediate (based on the **DBFallUp** field encoding in the **PWMnCTL** register), this 16-bit **DBFallUp** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 894). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 63: PWM0 Fault Source 0 (PWM0FLTSRC0), offset 0x074**

**Register 64: PWM1 Fault Source 0 (PWM1FLTSRC0), offset 0x0B4**

**Register 65: PWM2 Fault Source 0 (PWM2FLTSRC0), offset 0x0F4**

**Register 66: PWM3 Fault Source 0 (PWM3FLTSRC0), offset 0x134**

This register specifies which fault pin inputs are used to indicate a fault condition. Each bit in the following register indicates whether the corresponding fault pin is included in the fault condition. All enabled fault pins are ORed together to form the **PWMnFLTSRC0** portion of the fault condition. The **PWMnFLTSRC0** fault condition is then ORed with the **PWMnFLTSRC1** fault condition to generate the final fault condition for the PWM generator.

If the **FLTSRC** bit in the **PWMnCTL** register (see page 910) is clear, only the PWM **Fault0** pin affects the fault condition generated. Otherwise, sources defined in **PWMnFLTSRC0** and **PWMnFLTSRC1** affect the fault condition generated.

				Value Description
				0 Suppressed The comparator trigger output signal is suppressed and cannot generate a fault condition.
				1 Triggers Fault The comparator trigger output signal value is ORed with all other enabled trigger outputs.

**Register 71: PWM0 Minimum Fault Period (PWM0MINFLTPER), offset 0x07C**

**Register 72: PWM1 Minimum Fault Period (PWM1MINFLTPER), offset 0x0BC**

**Register 73: PWM2 Minimum Fault Period (PWM2MINFLTPER), offset 0x0FC**

**Register 74: PWM3 Minimum Fault Period (PWM3MINFLTPER), offset 0x13C**

If the `MINFLTPER` bit in the `PWMnCTL` register is set, this register specifies the 16-bit time-extension value to be used in extending the fault condition. The value is loaded into a 16-bit down counter, and the counter value is used to extend the fault condition. The fault condition is released in the clock immediately after the counter value reaches 0. The fault condition is asynchronous to the PWM clock; and the delay value is the product of the PWM clock period and the (MFP field value + 1) or (MFP field value + 2) depending on when the fault condition asserts with respect to the PWM clock. The counter decrements at the PWM clock rate, without pause or condition.

**Register 75: PWM0 Fault Pin Logic Sense (PWM0FLTSEN), offset 0x800**

**Register 76: PWM1 Fault Pin Logic Sense (PWM1FLTSEN), offset 0x880**

**Register 77: PWM2 Fault Pin Logic Sense (PWM2FLTSEN), offset 0x900**

**Register 78: PWM3 Fault Pin Logic Sense (PWM3FLTSEN), offset 0x980**

This register defines the PWM fault pin logic sense.

PWM0 Fault Pin Logic Sense (PWM0FLTSEN)

Base 0x4002.8000  
 Offset 0x800  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	FAULT3	R/W	0	Fault3 Sense  The same function as FLT0SEN, except applied for the FAULT3 input.
2	FAULT2	R/W	0	Fault2 Sense  The same function as FLT0SEN, except applied for the FAULT2 input.
1	FAULT1	R/W	0	Fault1 Sense  The same function as FLT0SEN, except applied for the FAULT1 input.
0	FAULT0	R/W	0	Fault0 Sense  This bit specifies the sense of the FAULT0 input pin, and it determines what sense is considered asserted, that is, the sense of the input (High or Low) that indicates error.  Value Description 0 High 1 Low  The fault sense is used to translate the incoming FAULT0 pin signal sense to an internal positive signal.

**Register 79: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804**

**Register 80: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884**

**Register 81: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904**

**Register 82: PWM3 Fault Status 0 (PWM3FLTSTAT0), offset 0x984**

Along with the **PWMnFLTSTAT1** register, this register provides status regarding the fault condition inputs.

If the **LATCH** bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT0** register are read-only (RO) and provide the current state of the **FAULTn** inputs.

If the **LATCH** bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT0** register are read / write 1 to clear (R/W1C) and provide a latched version of the **FAULTn** inputs. In this mode, the register bits are cleared by writing a 1 to a set bit. The **FAULTn** inputs are recorded after their sense is adjusted in the generator.

The contents of this register can only be written if the fault source extensions are enabled (the **FLTSRC** bit in the **PWMnCTL** register is set).

Bit/Field	Name	Type	Reset	Description
3	DCMP3	-	0	Digital Comparator 3 Trigger The same function as DCMP0, except applied for the Digital Comparator 3 trigger.
2	DCMP2	-	0	Digital Comparator 2 Trigger The same function as DCMP0, except applied for the Digital Comparator 2 trigger.
1	DCMP1	-	0	Digital Comparator 1 Trigger The same function as DCMP0, except applied for the Digital Comparator 1 trigger.
0	DCMP0	-	0	Digital Comparator 0 Trigger If the <b>PWMnCTL</b> register <b>LATCH</b> bit is clear, this bit represents the current state of the Digital Comparator 0 trigger input. If the <b>PWMnCTL</b> register <b>LATCH</b> bit is set, this bit represents a sticky version of the trigger. If the bit is set, the trigger transitioned to the active state previously. If clear, the trigger has not transitioned to the active state since the last time it was cleared. This bit is cleared by writing it with the value 1 (R/W1C).

## 23 Quadrature Encoder Interface (QEI)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The LM3S9792 microcontroller includes two quadrature encoder interface (QEI) modules. Each QEI module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

Each Stellaris<sup>®</sup> quadrature encoder has the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

### 23.1 Block Diagram

Figure 23-1 on page 943 provides a block diagram of a Stellaris<sup>®</sup> QEI module.

Figure 23-1. QEI Block Diagram

## 23.2 Functional Description

The QEI module interprets the two-bit gray code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The position integrator and velocity capture can be independently enabled, though the position integrator must be enabled before the velocity capture can be enabled. The two phase signals, PhA and PhB, can be swapped before being interpreted by the QEI module to change the meaning of forward and backward, and to correct for miswiring of the system. Alternatively, the phase signals can be interpreted as a clock and direction signal as output by some encoders.

The QEI module input signals have a digital noise filter on them that can be enabled to prevent spurious operation. The noise filter requires that the inputs be stable for 3 consecutive clock cycles before updating the edge detector. The filter is enabled by the `FILTEN` bit in the **QEI Control (QEICTL)** register. The frequency of the input update is programmable using the `FILTCNT` bit field in the **QEICTL** register.

The QEI module supports two modes of signal operation: quadrature phase mode and clock/direction mode. In quadrature phase mode, the encoder produces two clocks that are 90 degrees out of phase; the edge relationship is used to determine the direction of rotation. In clock/direction mode, the encoder produces a clock signal to indicate steps and a direction signal to indicate the direction of rotation. This mode is determined by the `SigMode` bit of the **QEI Control (QEICTL)** register (see page 947).

When the QEI module is set to use the quadrature phase mode (`SigMode` bit equals zero), the capture mode for the position integrator can be set to update the position counter on every edge of the PhA signal or to update on every edge of both PhA and PhB. Updating the position counter on every PhA and PhB provides more positional resolution at the cost of less range in the positional counter.

When edges on PhA lead edges on PhB , the position counter is incremented. When edges on PhB lead edges on PhA , the position counter is decremented. When a rising and falling edge pair is seen on one of the phases without any edges on the other, the direction of rotation has changed.

The positional counter is automatically reset on one of two conditions: sensing the index pulse or reaching the maximum position value. Which mode is determined by the ResMode bit of the **QEI Control (QEICTL)** register.

When ResMode is 0, the positional counter is reset when the index pulse is sensed. This limits the positional counter to the values [0:N-1], where N is the number of phase edges in a full revolution of the encoder wheel. The **QEIMAXPOS** register must be programmed with N-1 so that the reverse direction from position 0 can move the position counter to N-1. In this mode, the position register contains the absolute position of the encoder relative to the index (or home) position once an index pulse has been seen.

When ResMode is 1, the positional counter is constrained to the range [0:M], where M is the programmable maximum value. The index pulse is ignored by the positional counter in this mode.

The velocity capture has a configurable timer and a count register. It counts the number of phase edges (using the same configuration as for the position integrator) in a given time period. The edge count from the previous time period is available to the controller via the **QEISPEED** register, while the edge count for the current time period is being accumulated in the **QEICOUNT** register. As soon as the current time period is complete, the total number of edges counted in that time period is made available in the **QEISPEED** register (losing the previous value), the **QEICOUNT** is reset to 0, and counting commences on a new time period. The number of edges counted in a given time period is directly proportional to the velocity of the encoder.

Figure 23-2 on page 944 shows how the Stellaris® quadrature encoder converts the phase input signals into clock pulses, the direction signal, and how the velocity predivider operates (in Divide by 4 mode).

**Figure 23-2. Quadrature Encoder and Velocity Predivider Operation**

The period of the timer is configurable by specifying the load value for the timer in the **QEILOAD** register. When the timer reaches zero, an interrupt can be triggered, and the hardware reloads the timer with the **QEILOAD** value and continues to count down. At lower encoder speeds, a longer timer period is needed to be able to capture enough edges to have a meaningful result. At higher encoder speeds, both a shorter timer period and/or the velocity predivider can be used.

The following equation converts the velocity counter value into an rpm value:

$$\text{rpm} = (\text{clock} * (2 \wedge \text{VelDiv}) * \text{Speed} * 60) \div (\text{Load} * \text{ppr} * \text{edges})$$

where:

clock is the controller clock rate

ppr is the number of pulses per revolution of the physical encoder

edges is 2 or 4, based on the capture mode set in the **QEICTL** register (2 for `CapMode` set to 0 and 4 for `CapMode` set to 1)

For example, consider a motor running at 600 rpm. A 2048 pulse per revolution quadrature encoder is attached to the motor, producing 8192 phase edges per revolution. With a velocity predivider of  $\div 1$  (`VelDiv` set to 0) and clocking on both `PhA` and `PhB` edges, this results in 81,920 pulses per second (the motor turns 10 times per second). If the timer were clocked at 10,000 Hz, and the load value was 2,500 ( $\frac{1}{4}$  of a second), it would count 20,480 pulses per update. Using the above equation:

$$\text{rpm} = (10000 * 1 * 20480 * 60) \div (2500 * 2048 * 4) = 600 \text{ rpm}$$

Now, consider that the motor is sped up to 3000 rpm. This results in 409,600 pulses per second, or 102,400 every  $\frac{1}{4}$  of a second. Again, the above equation gives:

$$\text{rpm} = (10000 * 1 * 102400 * 60) \div (2500 * 2048 * 4) = 3000 \text{ rpm}$$

Care must be taken when evaluating this equation since intermediate values may exceed the capacity of a 32-bit integer. In the above examples, the clock is 10,000 and the divider is 2,500; both could be predivided by 100 (at compile time if they are constants) and therefore be 100 and 25. In fact, if they were compile-time constants, they could also be reduced to a simple multiply by 4, cancelled by the  $\div 4$  for the edge-count factor.

---

**Important:** Reducing constant factors at compile time is the best way to control the intermediate values of this equation, as well as reducing the processing requirement of computing this equation.

---

The division can be avoided by selecting a timer load value such that the divisor is a power of 2; a simple shift can therefore be done in place of the division. For encoders with a power of 2 pulses per revolution, this is a simple matter of selecting a power of 2 load value. For other encoders, a load value must be selected such that the product is very close to a power of two. For example, a 100 pulse per revolution encoder could use a load value of 82, resulting in 32,800 as the divisor, which is 0.09% above  $2^{14}$ ; in this case a shift by 15 would be an adequate approximation of the divide in most cases. If absolute accuracy were required, the controller's divide instruction could be used.

The QEI module can produce a controller interrupt on several events: phase error, direction change, reception of the index pulse, and expiration of the velocity timer. Standard masking, raw interrupt status, interrupt status, and interrupt clear capabilities are provided.

## 23.3 Initialization and Configuration

The following example shows how to configure the Quadrature Encoder module to read back an absolute position:

1. Enable the QEI clock by writing a value of 0x0000.0100 to the **RCGC1** register in the System Control module. See page 167.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module. See page 179.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register.
4. Configure the quadrature encoder to capture edges on both signals and maintain an absolute position by resetting on index pulses. Using a 1000-line encoder at four edges per line, there

are 4000 pulses per revolution; therefore, set the maximum position to 3999 (0xF9F) since the count is zero-based.

- Write the **QEICTL** register with the value of 0x0000.0018.
  - Write the **QEIMAXPOS** register with the value of 0x0000.0F9F.
5. Enable the quadrature encoder by setting bit 0 of the **QEICTL** register.
  6. Delay for some time.
  7. Read the encoder position by reading the **QEIPOS** register value.

## 23.4 Register Map

Table 23-1 on page 946 lists the QEI registers. The offset listed is a hexadecimal increment to the register's address, relative to the module's base address:

- QEI0: 0x4002.C000
- QEI1: 0x4002.D000

Note that the QEI module clock must be enabled before the registers can be programmed (see page 167).

**Table 23-1. QEI Register Map**

Offset	Name	Type	Reset	Description	See page

## 23.5 Register Descriptions

The remainder of this section lists and describes the QEI registers, in numerical order by address offset.

## Register 1: QEI Control (QEICTL), offset 0x000

This register contains the configuration of the QEI module. Separate enables are provided for the quadrature encoder and the velocity capture blocks; the quadrature encoder must be enabled in order to capture the velocity, but the velocity does not need to be captured in applications that do not need it. The phase signal interpretation, phase swap, Position Update mode, Position Reset mode, and velocity predivider are all set via this register.

### QEI Control (QEICTL)

31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
1	Direction	RO	0	Direction of Rotation Indicates the direction the encoder is rotating. The <code>Direction</code> values are defined as follows:  <table border="0"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>Forward rotation</td> </tr> <tr> <td>1</td> <td>Reverse rotation</td> </tr> </table>	Value	Description	0	Forward rotation	1	Reverse rotation
Value	Description									
0	Forward rotation									
1	Reverse rotation									
0	Error	RO	0	Error Detected Indicates that an error was detected in the gray code sequence (that is, both signals changing at the same time).						

### Register 3: QEI Position (QEIP0S), offset 0x008

This register contains the current value of the position integrator. Its value is updated by inputs on the QEI phase inputs, and can be set to a specific value by writing to it.

#### QEI Position (QEIP0S)

QEI0 base: 0x4002.C000  
 QEI1 base: 0x4002.D000  
 Offset 0x008  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	Position	R/W	0x00	Current Position Integrator Value The current value of the position integrator.

**Register 4: QEI Maximum Position (QEIMAXPOS), offset 0x00C**

This register contains the maximum value of the position integrator. When moving forward, the position register resets to zero when it increments past this value. When moving backward, the position register resets to this value when it decrements from zero.

## QEI Maximum Position (QEIMAXPOS)

QEI0 base: 0x4002.C000

QEI1 base: 0x4002.D000

Offset 0x00C

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MaxPos															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MaxPos															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	MaxPos	R/W	0x00	Maximum Position Integrator Value The maximum value of the position integrator.

### Register 5: QEI Timer Load (QEILOAD), offset 0x010

This register contains the load value for the velocity timer. Since this value is loaded into the timer the clock cycle after the timer is zero, this value should be one less than the number of clocks in the desired period. So, for example, to have 2000 clocks per timer period, this register should contain 1999.

#### QEI Timer Load (QEILOAD)

QEI0 base: 0x4002.C000  
 QEI1 base: 0x4002.D000  
 Offset 0x010  
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	Load	R/W	0x00	Velocity Timer Load Value The load value for the velocity timer.

## Register 6: QEI Timer (QEITIME), offset 0x014

This register contains the current value of the velocity timer. This counter does not increment when `VelEn` in `QEICTL` is 0.

### QEI Timer (QEITIME)

QEI0 base: 0x4002.C000

QEI1 base: 0x4002.D000

Offset 0x014

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Time															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Time															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	Time	RO	0x00	Velocity Timer Current Value The current value of the velocity timer.

### Register 7: QEI Velocity Counter (QEICOUNT), offset 0x018

This register contains the running count of velocity pulses for the current time period. Since this is a running total, the time period to which it applies cannot be known with precision (that is, a read of this register does not necessarily correspond to the time returned by the **QEITIME** register since there is a small window of time between the two reads, during which time either value may have changed). The **QEISPEED** register should be used to determine the actual encoder velocity; this register is provided for information purposes only. This counter does not increment when `VelEn` in **QEICTL** is 0.

#### QEI Velocity Counter (QEICOUNT)

QEI0 base: 0x4002.C000  
 QEI1 base: 0x4002.D000  
 Offset 0x018  
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	Count	RO	0x00	Velocity Pulse Count The running total of encoder pulses during this velocity timer period.

**Register 8: QEI Velocity (QEISPEED), offset 0x01C**

This register contains the most recently measured velocity of the quadrature encoder. This corresponds to the number of velocity pulses counted in the previous velocity timer period. This register does not update when `VelEn` in `QEICTL` is 0.

**QEI Velocity (QEISPEED)**

QEI0 base: 0x4002.C000

QEI1 base: 0x4002.D000

Offset 0x01C

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Speed															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	Speed	RO	0x00	Velocity

The measured speed of the quadrature encoder in pulses per period.

### Register 9: QEI Interrupt Enable (QEIINTEN), offset 0x020

This register contains enables for each of the QEI module's interrupts. An interrupt is asserted to the controller if its corresponding bit in this register is set to 1.

#### QEI Interrupt Enable (QEIINTEN)

QEI0 base: 0x4002.C000  
 QEI1 base: 0x4002.D000  
 Offset 0x020  
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved												IntError	IntDir	IntTimer	IntIndex	
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntError	R/W	0	Phase Error Interrupt Enable When 1, an interrupt occurs when a phase error is detected.
2	IntDir	R/W	0	Direction Change Interrupt Enable When 1, an interrupt occurs when the direction changes.
1	IntTimer	R/W	0	Timer Expires Interrupt Enable When 1, an interrupt occurs when the velocity timer expires.
0	IntIndex	R/W	0	Index Pulse Detected Interrupt Enable When 1, an interrupt occurs when the index pulse is detected.

## Register 10: QEI Raw Interrupt Status (QEIRIS), offset 0x024

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (this is set through the **QEINTEN** register). Bits set to 1 indicate the latched events that have occurred; a zero bit indicates that the event in question has not occurred.

### QEI Raw Interrupt Status (QEIRIS)

QEI0 base: 0x4002.C000

QEI1 base: 0x4002.D000

Offset 0x024

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved													IntError	IntDir	IntTimer	IntIndex
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntError	RO	0	Phase Error Detected Indicates that a phase error was detected.
2	IntDir	RO	0	Direction Change Detected Indicates that the direction has changed.
1	IntTimer	RO	0	Velocity Timer Expired Indicates that the velocity timer has expired.
0	IntIndex	RO	0	Index Pulse Asserted Indicates that the index pulse has occurred.

### Register 11: QEI Interrupt Status and Clear (QEIISC), offset 0x028

This register provides the current set of interrupt sources that are asserted to the controller. Bits set to 1 indicate the latched events that have occurred; a zero bit indicates that the event in question has not occurred. This is a R/W1C register; writing a 1 to a bit position clears the corresponding interrupt reason.

#### QEI Interrupt Status and Clear (QEIISC)

QEI0 base: 0x4002.C000  
 QEI1 base: 0x4002.D000  
 Offset 0x028  
 Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved												IntError	IntDir	IntTimer	IntIndex	
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W1C	R/W1C	R/W1C	R/W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	IntError	R/W1C	0	Phase Error Interrupt Indicates that a phase error was detected.
2	IntDir	R/W1C	0	Direction Change Interrupt Indicates that the direction has changed.
1	IntTimer	R/W1C	0	Velocity Timer Expired Interrupt Indicates that the velocity timer has expired.
0	IntIndex	R/W1C	0	Index Pulse Interrupt Indicates that the index pulse has occurred.

## 24 Pin Diagram

The LM3S9792 microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 25-5 on page 990.

**Figure 24-1. 100-Pin LQFP Package Pin Diagram**

## 25 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. For a GPIO pin to be used for an alternate function, the corresponding bit in the **GPIOAFSEL** register (see page 311) must be set. Further pin muxing options are provided through the  $PMC_x$  field in the **GPIOCTL** register (see page 328), which selects one of several available peripheral functions for that GPIO.

**Important:** All GPIO pins are configured as GPIOs by default with the exception of the pins shown in Table 9-1. A Power-On-Reset ( $\overline{POR}$ ) or asserting  $\overline{RST}$  puts the pins back to their default state.

**Table 25-1. GPIO Pins With Default Alternate Functions**

GPIO Pin	Default State	GPIOAFSEL Bit	GPIOCTL $PMC_x$ Bit Field
PA[1:0]	UART0	1	0x1
PA[5:2]	SSI0	1	0x1
PB[3:2]	I <sup>2</sup> C0	1	0x1
PC[3:0]	JTAG/SWD	1	0x3

Table 25-2 on page 960 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate function is listed for each pin.

Table 25-3 on page 971 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the  $PMC_x$  bit field in the **GPIOCTL** register.

Table 25-4 on page 981 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 25-5 on page 990 lists the GPIO pins and their alternate functions. The table heading "enc=" shows what the appropriate encoding for  $PMC_x$  should be to select the function in that column (see page 328). Table entries that are shaded gray are the default values for the corresponding GPIO pin.

**Table 25-2. Signals by Pin Number**

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
1	PE7	I/O	TTL	GPIO port E bit 7.
	AIN0	I	Analog	ADC 0 input.
	PWM5	O	TTL	PWM 5.
	C2o	O	TTL	Analog comparator 2 output.
	U1DCD	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
2	PE6	I/O	TTL	GPIO port E bit 6.
	AIN1	I	Analog	ADC 1 input.
	PWM4	O	TTL	PWM 4.
	C1o	O	TTL	Analog comparator 1 output.
	U1CTS	I	TTL	UART module 1 Clear To Send modem status input signal.

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
3	VDDA	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.
4	GNDA	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
5	PE5	I/O	TTL	GPIO port E bit 5.
	AIN2	I	Analog	ADC 2 input.
	CCP5	I/O	TTL	Capture/Compare/PWM 5.
	I2S0TXSD	I/O	TTL	I <sup>2</sup> S module 0 transmit data.
6	PE4	I/O	TTL	GPIO port E bit 4.
	AIN3	I	Analog	ADC 3 input.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
	Fault0	I	TTL	PWM Fault 0.
	U2Tx	O	TTL	UART module 2 transmit.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
	I2S0TXWS	I/O	TTL	I <sup>2</sup> S module 0 transmit word select.
7	LDO	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDDC pins at the board level in addition to the decoupling capacitor(s).
8	VDD	-	Power	Positive supply for I/O and some logic.
9	GND	-	Power	Ground reference for logic and I/O pins.
10	PD0	I/O	TTL	GPIO port D bit 0.
	AIN15	I	Analog	ADC 15 input.
	PWM0	O	TTL	PWM 0.
	CAN0Rx	I	TTL	CAN module 0 receive.
	IDX0	I	TTL	QEI module 0 index.
	U2Rx	I	TTL	UART module 2 receive.
	U1Rx	I	TTL	UART module 1 receive.
	CCP6	I/O	TTL	Capture/Compare/PWM 6.
	I2S0RXSCK	I/O	TTL	I <sup>2</sup> S module 0 receive clock.
U1CTS	I	TTL	UART module 1 Clear To Send modem status input signal.	

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
11	PD1	I/O	TTL	GPIO port D bit 1.
	AIN14	I	Analog	ADC 14 input.
	PWM1	O	TTL	PWM 1.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	PhA0	I	TTL	QEI module 0 phase A.
	U2Tx	O	TTL	UART module 2 transmit.
	U1Tx	O	TTL	UART module 1 transmit.
	CCP7	I/O	TTL	Capture/Compare/PWM 7.
	I2S0RXWS	I/O	TTL	I <sup>2</sup> S module 0 receive word select.
	U1DCD	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
PhB1	I	TTL	QEI module 1 phase B.	
12	PD2	I/O	TTL	GPIO port D bit 2.
	AIN13	I	Analog	ADC 13 input.
	U1Rx	I	TTL	UART module 1 receive.
	CCP6	I/O	TTL	Capture/Compare/PWM 6.
	PWM2	O	TTL	PWM 2.
	CCP5	I/O	TTL	Capture/Compare/PWM 5.
	EPI0S20	I/O	TTL	EPI module 0 signal 20.
13	PD3	I/O	TTL	GPIO port D bit 3.
	AIN12	I	Analog	ADC 12 input.
	U1Tx	O	TTL	UART module 1 transmit.
	CCP7	I/O	TTL	Capture/Compare/PWM 7.
	PWM3	O	TTL	PWM 3.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
	EPI0S21	I/O	TTL	EPI module 0 signal 21.
14	PJ0	I/O	TTL	GPIO port J bit 0.
	EPI0S16	I/O	TTL	EPI module 0 signal 16.
	PWM0	O	TTL	PWM 0.
	I2C1SCL	I/O	OD	I <sup>2</sup> C module 1 clock.
15	PH7	I/O	TTL	GPIO port H bit 7.
	EPI0S27	I/O	TTL	EPI module 0 signal 27.
	PWM5	O	TTL	PWM 5.
	SSI1Tx	O	TTL	SSI module 1 transmit.
16	XTALPPHY	O	Analog	XTALP of the Ethernet PHY.
17	XTALNPHY	I	Analog	XTALN of the Ethernet PHY.
18	PG1	I/O	TTL	GPIO port G bit 1.
	U2Tx	O	TTL	UART module 2 transmit.
	PWM1	O	TTL	PWM 1.
	I2C1SDA	I/O	OD	I <sup>2</sup> C module 1 data.
	PWM5	O	TTL	PWM 5.
	EPI0S14	I/O	TTL	EPI module 0 signal 14.

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
19	PG0	I/O	TTL	GPIO port G bit 0.
	U2Rx	I	TTL	UART module 2 receive.
	PWM0	O	TTL	PWM 0.
	I2C1SCL	I/O	OD	I <sup>2</sup> C module 1 clock.
	PWM4	O	TTL	PWM 4.
	USB0EPEN	O	TTL	Used in Host mode to control an external power source to supply power to the USB bus.
	EPI0S13	I/O	TTL	EPI module 0 signal 13.
20	VDD	-	Power	Positive supply for I/O and some logic.
21	GND	-	Power	Ground reference for logic and I/O pins.
22	PC7	I/O	TTL	GPIO port C bit 7.
	C2-	I	Analog	Analog comparator 2 negative input.
	CCP4	I/O	TTL	Capture/Compare/PWM 4.
	PhB0	I	TTL	QEI module 0 phase B.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
	U1Tx	O	TTL	UART module 1 transmit.
	USB0PFLT	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.
	C1o	O	TTL	Analog comparator 1 output.
23	EPI0S5	I/O	TTL	EPI module 0 signal 5.
	PC6	I/O	TTL	GPIO port C bit 6.
	C2+	I	Analog	Analog comparator 2 positive input.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
	PhB0	I	TTL	QEI module 0 phase B.
	C2o	O	TTL	Analog comparator 2 output.
	PWM7	O	TTL	PWM 7.
	U1Rx	I	TTL	UART module 1 receive.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
USB0PFLT	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.	
24	EPI0S4	I/O	TTL	EPI module 0 signal 4.
	PC5	I/O	TTL	GPIO port C bit 5.
	C1+	I	Analog	Analog comparator 1 positive input.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
	C1o	O	TTL	Analog comparator 1 output.
	C0o	O	TTL	Analog comparator 0 output.
	Fault2	I	TTL	PWM Fault 2.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
USB0EPEN	O	TTL	Used in Host mode to control an external power source to supply power to the USB bus.	
EPI0S3	I/O	TTL	EPI module 0 signal 3.	

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
25	PC4	I/O	TTL	GPIO port C bit 4.
	CCP5	I/O	TTL	Capture/Compare/PWM 5.
	PhA0	I	TTL	QEI module 0 phase A.
	PWM6	O	TTL	PWM 6.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
	CCP4	I/O	TTL	Capture/Compare/PWM 4.
	EPI0S2	I/O	TTL	EPI module 0 signal 2.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
26	PA0	I/O	TTL	GPIO port A bit 0.
	U0Rx	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
	I2C1SCL	I/O	OD	I <sup>2</sup> C module 1 clock.
	U1Rx	I	TTL	UART module 1 receive.
27	PA1	I/O	TTL	GPIO port A bit 1.
	U0Tx	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
	I2C1SDA	I/O	OD	I <sup>2</sup> C module 1 data.
	U1Tx	O	TTL	UART module 1 transmit.
28	PA2	I/O	TTL	GPIO port A bit 2.
	SSI0Clk	I/O	TTL	SSI module 0 clock.
	PWM4	O	TTL	PWM 4.
	I2S0RXSD	I/O	TTL	I <sup>2</sup> S module 0 receive data.
29	PA3	I/O	TTL	GPIO port A bit 3.
	SSI0Fss	I/O	TTL	SSI module 0 frame.
	PWM5	O	TTL	PWM 5.
	I2S0RXMCLK	I/O	TTL	I <sup>2</sup> S module 0 receive master clock.
30	PA4	I/O	TTL	GPIO port A bit 4.
	SSI0Rx	I	TTL	SSI module 0 receive.
	PWM6	O	TTL	PWM 6.
	CAN0Rx	I	TTL	CAN module 0 receive.
	I2S0TXSCK	I/O	TTL	I <sup>2</sup> S module 0 transmit clock.
31	PA5	I/O	TTL	GPIO port A bit 5.
	SSI0Tx	O	TTL	SSI module 0 transmit.
	PWM7	O	TTL	PWM 7.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	I2S0TXWS	I/O	TTL	I <sup>2</sup> S module 0 transmit word select.
32	VDD	-	Power	Positive supply for I/O and some logic.
33	ERBIAS	O	Analog	9.1-k $\Omega$ resistor (1% precision) used internally for Ethernet PHY.

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
34	PA6	I/O	TTL	GPIO port A bit 6.
	I2C1SCL	I/O	OD	I <sup>2</sup> C module 1 clock.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
	PWM0	O	TTL	PWM 0.
	PWM4	O	TTL	PWM 4.
	CAN0Rx	I	TTL	CAN module 0 receive.
	USB0EPEN	O	TTL	Used in Host mode to control an external power source to supply power to the USB bus.
	U1CTS	I	TTL	UART module 1 Clear To Send modem status input signal.
35	PA7	I/O	TTL	GPIO port A bit 7.
	I2C1SDA	I/O	OD	I <sup>2</sup> C module 1 data.
	CCP4	I/O	TTL	Capture/Compare/PWM 4.
	PWM1	O	TTL	PWM 1.
	PWM5	O	TTL	PWM 5.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
	USB0PFLT	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.
U1DCD	I	TTL	UART module 1 Data Carrier Detect modem status input signal.	
36	PG7	I/O	TTL	GPIO port G bit 7.
	PhB1	I	TTL	QEI module 1 phase B.
	PWM7	O	TTL	PWM 7.
	CCP5	I/O	TTL	Capture/Compare/PWM 5.
	EPI0S31	I/O	TTL	EPI module 0 signal 31.
37	RXIN	I	Analog	RXIN of the Ethernet PHY.
38	VDDC	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
39	PJ2	I/O	TTL	GPIO port J bit 2.
	EPI0S18	I/O	TTL	EPI module 0 signal 18.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
	Fault0	I	TTL	PWM Fault 0.
40	RXIP	I	Analog	RXIP of the Ethernet PHY.
41	PF5	I/O	TTL	GPIO port F bit 5.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
	C1o	O	TTL	Analog comparator 1 output.
	EPI0S15	I/O	TTL	EPI module 0 signal 15.
	SSI1Tx	O	TTL	SSI module 1 transmit.
42	PF4	I/O	TTL	GPIO port F bit 4.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
	C0o	O	TTL	Analog comparator 0 output.
	Fault0	I	TTL	PWM Fault 0.
	EPI0S12	I/O	TTL	EPI module 0 signal 12.
	SSI1Rx	I	TTL	SSI module 1 receive.

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
43	TXOP	O	TTL	TXOP of the Ethernet PHY.
44	VDD	-	Power	Positive supply for I/O and some logic.
45	GND	-	Power	Ground reference for logic and I/O pins.
46	TXON	O	TTL	TXON of the Ethernet PHY.
47	PF0	I/O	TTL	GPIO port F bit 0.
	CAN1Rx	I	TTL	CAN module 1 receive.
	PhB0	I	TTL	QEI module 0 phase B.
	PWM0	O	TTL	PWM 0.
	I2S0TXSD	I/O	TTL	I <sup>2</sup> S module 0 transmit data.
	U1DSR	I	TTL	UART module 1 Data Set Ready modem output control line.
48	OSC0	I	Analog	Main oscillator crystal input or an external clock reference input.
49	OSC1	O	Analog	Main oscillator crystal output.
50	PJ3	I/O	TTL	GPIO port J bit 3.
	EPI0S19	I/O	TTL	EPI module 0 signal 19.
	U1CTS	I	TTL	UART module 1 Clear To Send modem status input signal.
	CCP6	I/O	TTL	Capture/Compare/PWM 6.
51	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
52	PJ4	I/O	TTL	GPIO port J bit 4.
	EPI0S28	I/O	TTL	EPI module 0 signal 28.
	U1DCD	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
	CCP4	I/O	TTL	Capture/Compare/PWM 4.
53	PJ5	I/O	TTL	GPIO port J bit 5.
	EPI0S29	I/O	TTL	EPI module 0 signal 29.
	U1DSR	I	TTL	UART module 1 Data Set Ready modem output control line.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
54	PJ6	I/O	TTL	GPIO port J bit 6.
	EPI0S30	I/O	TTL	EPI module 0 signal 30.
	U1RTS	O	TTL	UART module 1 Request to Send modem output control line.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
55	PJ7	I/O	TTL	GPIO port J bit 7.
	U1DTR	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
56	VDD	-	Power	Positive supply for I/O and some logic.
57	GND	-	Power	Ground reference for logic and I/O pins.
58	MDIO	I/O	OD	MDIO of the Ethernet PHY.
59	PF3	I/O	TTL	GPIO port F bit 3.
	LED0	O	TTL	MII LED 0.
	PWM5	O	TTL	PWM 5.
	PWM3	O	TTL	PWM 3.
	SSI1F <sub>SS</sub>	I/O	TTL	SSI module 1 frame.

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
60	PF2	I/O	TTL	GPIO port F bit 2.
	LED1	O	TTL	MII LED 1.
	PWM4	O	TTL	PWM 4.
	PWM2	O	TTL	PWM 2.
	SSI1Clk	I/O	TTL	SSI module 1 clock.
61	PF1	I/O	TTL	GPIO port F bit 1.
	CAN1Tx	O	TTL	CAN module 1 transmit.
	IDX1	I	TTL	QEI module 1 index.
	PWM1	O	TTL	PWM 1.
	I2S0TXMCLK	I/O	TTL	I <sup>2</sup> S module 0 transmit master clock.
	U1RTS	O	TTL	UART module 1 Request to Send modem output control line.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
62	PH6	I/O	TTL	GPIO port H bit 6.
	EPI0S26	I/O	TTL	EPI module 0 signal 26.
	PWM4	O	TTL	PWM 4.
	SSI1Rx	I	TTL	SSI module 1 receive.
63	PH5	I/O	TTL	GPIO port H bit 5.
	EPI0S11	I/O	TTL	EPI module 0 signal 11.
	Fault2	I	TTL	PWM Fault 2.
	SSI1Fss	I/O	TTL	SSI module 1 frame.
64	RST	I	TTL	System reset input.
65	PB3	I/O	TTL	GPIO port B bit 3.
	I2C0SDA	I/O	OD	I <sup>2</sup> C module 0 data.
	Fault0	I	TTL	PWM Fault 0.
	Fault3	I	TTL	PWM Fault 3.
	USB0PFLT	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.
66	PB0	I/O	TTL	GPIO port B bit 0.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
	PWM2	O	TTL	PWM 2.
	U1Rx	I	TTL	UART module 1 receive.
	USB0ID	I	Analog	This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is an A device and not pulled down is a B device).
67	PB1	I/O	TTL	GPIO port B bit 1.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
	PWM3	O	TTL	PWM 3.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
	U1Tx	O	TTL	UART module 1 transmit.
	USB0VBUS	I/O	Analog	This signal is used during the session negotiation protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.
68	VDD	-	Power	Positive supply for I/O and some logic.

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
69	GND	-	Power	Ground reference for logic and I/O pins.
70	USB0DM	I/O	Analog	Bidirectional differential data pin (D- per USB specification).
71	USB0DP	I/O	Analog	Bidirectional differential data pin (D+ per USB specification).
72	PB2	I/O	TTL	GPIO port B bit 2.
	I2C0SCL	I/O	OD	I <sup>2</sup> C module 0 clock.
	IDX0	I	TTL	QEI module 0 index.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
	USB0EPEN	O	TTL	Used in Host mode to control an external power source to supply power to the USB bus.
73	USB0RBIAS	O	Analog	9.1-k $\Omega$ resistor (1% precision) used internally for USB analog circuitry.
74	PE0	I/O	TTL	GPIO port E bit 0.
	PWM4	O	TTL	PWM 4.
	SSI1Clk	I/O	TTL	SSI module 1 clock.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
	EPI0S8	I/O	TTL	EPI module 0 signal 8.
	USB0PFLT	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.
75	PE1	I/O	TTL	GPIO port E bit 1.
	PWM5	O	TTL	PWM 5.
	SSI1Fss	I/O	TTL	SSI module 1 frame.
	Fault0	I	TTL	PWM Fault 0.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
	CCP6	I/O	TTL	Capture/Compare/PWM 6.
	EPI0S9	I/O	TTL	EPI module 0 signal 9.
76	PH4	I/O	TTL	GPIO port H bit 4.
	USB0PFLT	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.
	EPI0S10	I/O	TTL	EPI module 0 signal 10.
	SSI1Clk	I/O	TTL	SSI module 1 clock.
77	PC3	I/O	TTL	GPIO port C bit 3.
	TDO	O	TTL	JTAG TDO and SWO.
	SWO	O	TTL	JTAG TDO and SWO.
78	PC2	I/O	TTL	GPIO port C bit 2.
	TDI	I	TTL	JTAG TDI.
79	PC1	I/O	TTL	GPIO port C bit 1.
	TMS	I	TTL	JTAG TMS and SWDIO.
	SWDIO	I/O	TTL	JTAG TMS and SWDIO.
80	PC0	I/O	TTL	GPIO port C bit 0.
	TCK	I	TTL	JTAG/SWD CLK.
	SWCLK	I	TTL	JTAG/SWD CLK.
81	VDD	-	Power	Positive supply for I/O and some logic.
82	GND	-	Power	Ground reference for logic and I/O pins.

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
83	PH3	I/O	TTL	GPIO port H bit 3.
	PhB0	I	TTL	QEI module 0 phase B.
	Fault0	I	TTL	PWM Fault 0.
	USB0EPEN	O	TTL	Used in Host mode to control an external power source to supply power to the USB bus.
	EPI0S0	I/O	TTL	EPI module 0 signal 0.
84	PH2	I/O	TTL	GPIO port H bit 2.
	IDX1	I	TTL	QEI module 1 index.
	C1o	O	TTL	Analog comparator 1 output.
	Fault3	I	TTL	PWM Fault 3.
	EPI0S1	I/O	TTL	EPI module 0 signal 1.
85	PH1	I/O	TTL	GPIO port H bit 1.
	CCP7	I/O	TTL	Capture/Compare/PWM 7.
	PWM3	O	TTL	PWM 3.
	EPI0S7	I/O	TTL	EPI module 0 signal 7.
	PWM5	O	TTL	PWM 5.
86	PH0	I/O	TTL	GPIO port H bit 0.
	CCP6	I/O	TTL	Capture/Compare/PWM 6.
	PWM2	O	TTL	PWM 2.
	EPI0S6	I/O	TTL	EPI module 0 signal 6.
	PWM4	O	TTL	PWM 4.
87	PJ1	I/O	TTL	GPIO port J bit 1.
	EPI0S17	I/O	TTL	EPI module 0 signal 17.
	USB0PFLT	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.
	PWM1	O	TTL	PWM 1.
	I2C1SDA	I/O	OD	I <sup>2</sup> C module 1 data.
88	VDDC	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
89	PB7	I/O	TTL	GPIO port B bit 7.
	NMI	I	TTL	Non-maskable interrupt.

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
90	PB6	I/O	TTL	GPIO port B bit 6.
	VREFA	I	Analog	This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AIN <sub>n</sub> signal is converted to 1023. The VREFA input is limited to the range specified in Table 27-2 on page 993.
	C0+	I	Analog	Analog comparator 0 positive input.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
	CCP7	I/O	TTL	Capture/Compare/PWM 7.
	C0o	O	TTL	Analog comparator 0 output.
	Fault1	I	TTL	PWM Fault 1.
	IDX0	I	TTL	QEI module 0 index.
	CCP5	I/O	TTL	Capture/Compare/PWM 5.
I2S0TXSCK	I/O	TTL	I <sup>2</sup> S module 0 transmit clock.	
91	PB5	I/O	TTL	GPIO port B bit 5.
	AIN11	I	Analog	ADC 11 input.
	C1-	I	Analog	Analog comparator 1 negative input.
	C0o	O	TTL	Analog comparator 0 output.
	CCP5	I/O	TTL	Capture/Compare/PWM 5.
	CCP6	I/O	TTL	Capture/Compare/PWM 6.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
	U1Tx	O	TTL	UART module 1 transmit.
EPI0S22	I/O	TTL	EPI module 0 signal 22.	
92	PB4	I/O	TTL	GPIO port B bit 4.
	AIN10	I	Analog	ADC 10 input.
	C0-	I	Analog	Analog comparator 0 negative input.
	U2Rx	I	TTL	UART module 2 receive.
	CAN0Rx	I	TTL	CAN module 0 receive.
	IDX0	I	TTL	QEI module 0 index.
	U1Rx	I	TTL	UART module 1 receive.
EPI0S23	I/O	TTL	EPI module 0 signal 23.	
93	VDD	-	Power	Positive supply for I/O and some logic.
94	GND	-	Power	Ground reference for logic and I/O pins.
95	PE2	I/O	TTL	GPIO port E bit 2.
	AIN9	I	Analog	ADC 9 input.
	CCP4	I/O	TTL	Capture/Compare/PWM 4.
	SSI1Rx	I	TTL	SSI module 1 receive.
	PhB1	I	TTL	QEI module 1 phase B.
	PhA0	I	TTL	QEI module 0 phase A.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
EPI0S24	I/O	TTL	EPI module 0 signal 24.	

Pin Number	Pin Name	Pin Type	Buffer Type <sup>a</sup>	Description
96	PE3	I/O	TTL	GPIO port E bit 3.
	AIN8	I	Analog	ADC 8 input.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
	SSI1Tx	O	TTL	SSI module 1 transmit.
	PhA1	I	TTL	QEI module 1 phase A.
	PhB0	I	TTL	QEI module 0 phase B.
	CCP7	I/O	TTL	Capture/Compare/PWM 7.
	EPI0S25	I/O	TTL	EPI module 0 signal 25.
97	PD4	I/O	TTL	GPIO port D bit 4.
	AIN7	I	Analog	ADC 7 input.
	CCP0	I/O	TTL	Capture/Compare/PWM 0.
	CCP3	I/O	TTL	Capture/Compare/PWM 3.
	I2S0RXSD	I/O	TTL	I <sup>2</sup> S module 0 receive data.
	U1RI	I	TTL	UART module 1 Ring Indicator modem status input signal.
	EPI0S19	I/O	TTL	EPI module 0 signal 19.
98	PD5	I/O	TTL	GPIO port D bit 5.
	AIN6	I	Analog	ADC 6 input.
	CCP2	I/O	TTL	Capture/Compare/PWM 2.
	CCP4	I/O	TTL	Capture/Compare/PWM 4.
	I2S0RXMCLK	I/O	TTL	I <sup>2</sup> S module 0 receive master clock.
	U2Rx	I	TTL	UART module 2 receive.
	EPI0S28	I/O	TTL	EPI module 0 signal 28.
99	PD6	I/O	TTL	GPIO port D bit 6.
	AIN5	I	Analog	ADC 5 input.
	Fault0	I	TTL	PWM Fault 0.
	I2S0TXSCK	I/O	TTL	I <sup>2</sup> S module 0 transmit clock.
	U2Tx	O	TTL	UART module 2 transmit.
	EPI0S29	I/O	TTL	EPI module 0 signal 29.
100	PD7	I/O	TTL	GPIO port D bit 7.
	AIN4	I	Analog	ADC 4 input.
	IDX0	I	TTL	QEI module 0 index.
	CO <sub>o</sub>	O	TTL	Analog comparator 0 output.
	CCP1	I/O	TTL	Capture/Compare/PWM 1.
	I2S0TXWS	I/O	TTL	I <sup>2</sup> S module 0 transmit word select.
	U1DTR	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
	EPI0S30	I/O	TTL	EPI module 0 signal 30.

a. The TTL designation indicates the pin is TTL-compatible.

**Table 25-3. Signals by Signal Name**

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description
AIN0	1	-	I	Analog	ADC 0 input.
AIN1	2	-	I	Analog	ADC 1 input.

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description
AIN2	5	-	I	Analog	ADC 2 input.
AIN3	6	-	I	Analog	ADC 3 input.
AIN4	100	-	I	Analog	ADC 4 input.
AIN5	99	-	I	Analog	ADC 5 input.
AIN6	98	-	I	Analog	ADC 6 input.
AIN7	97	-	I	Analog	ADC 7 input.
AIN8	96	-	I	Analog	ADC 8 input.
AIN9	95	-	I	Analog	ADC 9 input.
AIN10	92	-	I	Analog	ADC 10 input.
AIN11	91	-	I	Analog	ADC 11 input.
AIN12	13	-	I	Analog	ADC 12 input.
AIN13	12	-	I	Analog	ADC 13 input.
AIN14	11	-	I	Analog	ADC 14 input.
AIN15	10	-	I	Analog	ADC 15 input.
C0+	90	-	I	Analog	Analog comparator 0 positive input.
C0-	92	-	I	Analog	Analog comparator 0 negative input.
C0o	24 42 90 91 100	PC5 (3) PF4 (2) PB6 (3) PB5 (1) PD7 (2)	O	TTL	Analog comparator 0 output.
C1+	24	-	I	Analog	Analog comparator 1 positive input.
C1-	91	-	I	Analog	Analog comparator 1 negative input.
C1o	2 22 24 41 84	PE6 (2) PC7 (7) PC5 (2) PF5 (2) PH2 (2)	O	TTL	Analog comparator 1 output.
C2+	23	-	I	Analog	Analog comparator 2 positive input.
C2-	22	-	I	Analog	Analog comparator 2 negative input.
C2o	1 23	PE7 (2) PC6 (3)	O	TTL	Analog comparator 2 output.
CAN0Rx	10 30 34 92	PD0 (2) PA4 (5) PA6 (6) PB4 (5)	I	TTL	CAN module 0 receive.
CAN0Tx	11 31 35 91	PD1 (2) PA5 (5) PA7 (6) PB5 (5)	O	TTL	CAN module 0 transmit.
CAN1Rx	47	PF0 (1)	I	TTL	CAN module 1 receive.
CAN1Tx	61	PF1 (1)	O	TTL	CAN module 1 transmit.

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description

EPI0S20	12	PD2 (8)	I/O	TTL	EPI module 0 signal 20.
EPI0S21	13	PD3 (8)	I/O	TTL	EPI module 0 signal 21.
EPI0S22	91	PB5 (8)	I/O	TTL	EPI module 0 signal 22.
EPI0S23	92	PB4 (8)	I/O	TTL	EPI module 0 signal 23.
EPI0S24	95	PE2 (8)	I/O	TTL	EPI module 0 signal 24.
EPI0S25	96	PE3 (8)	I/O	TTL	EPI module 0 signal 25.
EPI0S26	62	PH6 (8)	I/O	TTL	EPI module 0 signal 26.
EPI0S27	15	PH7 (8)	I/O	TTL	EPI module 0 signal 27.
EPI0S28	52 98	PJ4 (8) PD5 (10)	I/O	TTL	EPI module 0 signal 28.
EPI0S29	53 99	PJ5 (8) PD6 (10)	I/O	TTL	EPI module 0 signal 29.
EPI0S30	54 100	PJ6 (8) PD7 (10)	I/O	TTL	EPI module 0 signal 30.
EPI0S31	36	PG7 (9)	I/O	TTL	EPI module 0 signal 31.
ERBIAS	33	-	O	Analog	9.1-kΩ resistor (1% precision) used internally for Ethernet PHY.

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description
Fault0	6	PE4 (4)	I	TTL	PWM Fault 0.
	39	PJ2 (10)			
	42	PF4 (4)			
	65	PB3 (2)			
	75	PE1 (3)			
	83	PH3 (2)			
	99	PD6 (1)			
Fault1	90	PB6 (4)	I	TTL	PWM Fault 1.
Fault2	24	PC5 (4)	I	TTL	PWM Fault 2.
	63	PH5 (10)			
Fault3	65	PB3 (4)	I	TTL	PWM Fault 3.
	84	PH2 (4)			
GND	9	-	-	Power	Ground reference for logic and I/O pins.
	21				
	45				
	57				
	69				
	82				
	94				
GND A	4	-	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
I2C0SCL	72	PB2 (1)	I/O	OD	I <sup>2</sup> C module 0 clock.
I2C0SDA	65	PB3 (1)	I/O	OD	I <sup>2</sup> C module 0 data.
I2C1SCL	14	PJ0 (11)	I/O	OD	I <sup>2</sup> C module 1 clock.
	19	PG0 (3)			
	26	PA0 (8)			
	34	PA6 (1)			
I2C1SDA	18	PG1 (3)	I/O	OD	I <sup>2</sup> C module 1 data.
	27	PA1 (8)			
	35	PA7 (1)			
	87	PJ1 (11)			
I2S0RXMCLK	29	PA3 (9)	I/O	TTL	I <sup>2</sup> S module 0 receive master clock.
	98	PD5 (8)			
I2S0RXSCK	10	PD0 (8)	I/O	TTL	I <sup>2</sup> S module 0 receive clock.
I2S0RXSD	28	PA2 (9)	I/O	TTL	I <sup>2</sup> S module 0 receive data.
	97	PD4 (8)			
I2S0RXWS	11	PD1 (8)	I/O	TTL	I <sup>2</sup> S module 0 receive word select.
I2S0TXMCLK	61	PF1 (8)	I/O	TTL	I <sup>2</sup> S module 0 transmit master clock.
I2S0TXSCK	30	PA4 (9)	I/O	TTL	I <sup>2</sup> S module 0 transmit clock.
	90	PB6 (9)			
	99	PD6 (8)			
I2S0TXSD	5	PE5 (9)	I/O	TTL	I <sup>2</sup> S module 0 transmit data.
	47	PF0 (8)			
I2S0TXWS	6	PE4 (9)	I/O	TTL	I <sup>2</sup> S module 0 transmit word select.
	31	PA5 (9)			
	100	PD7 (8)			
IDX0	10	PD0 (3)	I	TTL	QE1 module 0 index.
	72	PB2 (2)			
	90	PB6 (5)			
	92	PB4 (6)			
	100	PD7 (1)			

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description
IDX1	61 84	PF1 (2) PH2 (1)	I	TTL	QE1 module 1 index.
LDO	7	-	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the $V_{DDC}$ pins at the board level in addition to the decoupling capacitor(s).
LED0	59	PF3 (1)	O	TTL	MII LED 0.
LED1	60	PF2 (1)	O	TTL	MII LED 1.
MDIO	58	-	I/O	OD	MDIO of the Ethernet PHY.
NC	51	-	-	-	No connect. Leave the pin electrically unconnected/isolated.
NMI	89	PB7 (4)	I	TTL	Non-maskable interrupt.
OSC0	48	-	I	Analog	Main oscillator crystal input or an external clock reference input.
OSC1	49	-	O	Analog	Main oscillator crystal output.
PA0	26	-	I/O	TTL	GPIO port A bit 0.
PA1	27	-	I/O	TTL	GPIO port A bit 1.
PA2	28	-	I/O	TTL	GPIO port A bit 2.
PA3	29	-	I/O	TTL	GPIO port A bit 3.
PA4	30	-	I/O	TTL	GPIO port A bit 4.
PA5	31	-	I/O	TTL	GPIO port A bit 5.
PA6	34	-	I/O	TTL	GPIO port A bit 6.
PA7	35	-	I/O	TTL	GPIO port A bit 7.
PB0	66	-	I/O	TTL	GPIO port B bit 0.
PB1	67	-	I/O	TTL	GPIO port B bit 1.
PB2	72	-	I/O	TTL	GPIO port B bit 2.
PB3	65	-	I/O	TTL	GPIO port B bit 3.
PB4	92	-	I/O	TTL	GPIO port B bit 4.
PB5	91	-	I/O	TTL	GPIO port B bit 5.
PB6	90	-	I/O	TTL	GPIO port B bit 6.
PB7	89	-	I/O	TTL	GPIO port B bit 7.
PC0	80	-	I/O	TTL	GPIO port C bit 0.
PC1	79	-	I/O	TTL	GPIO port C bit 1.
PC2	78	-	I/O	TTL	GPIO port C bit 2.
PC3	77	-	I/O	TTL	GPIO port C bit 3.
PC4	25	-	I/O	TTL	GPIO port C bit 4.
PC5	24	-	I/O	TTL	GPIO port C bit 5.
PC6	23	-	I/O	TTL	GPIO port C bit 6.
PC7	22	-	I/O	TTL	GPIO port C bit 7.
PD0	10	-	I/O	TTL	GPIO port D bit 0.
PD1	11	-	I/O	TTL	GPIO port D bit 1.
PD2	12	-	I/O	TTL	GPIO port D bit 2.
PD3	13	-	I/O	TTL	GPIO port D bit 3.

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description
PD4	97	-	I/O	TTL	GPIO port D bit 4.
PD5	98	-	I/O	TTL	GPIO port D bit 5.
PD6	99	-	I/O	TTL	GPIO port D bit 6.
PD7	100	-	I/O	TTL	GPIO port D bit 7.
PE0	74	-	I/O	TTL	GPIO port E bit 0.
PE1	75	-	I/O	TTL	GPIO port E bit 1.
PE2	95	-	I/O	TTL	GPIO port E bit 2.
PE3	96	-	I/O	TTL	GPIO port E bit 3.
PE4	6	-	I/O	TTL	GPIO port E bit 4.
PE5	5	-	I/O	TTL	GPIO port E bit 5.
PE6	2	-	I/O	TTL	GPIO port E bit 6.
PE7	1	-	I/O	TTL	GPIO port E bit 7.
PF0	47	-	I/O	TTL	GPIO port F bit 0.
PF1	61	-	I/O	TTL	GPIO port F bit 1.
PF2	60	-	I/O	TTL	GPIO port F bit 2.
PF3	59	-	I/O	TTL	GPIO port F bit 3.
PF4	42	-	I/O	TTL	GPIO port F bit 4.
PF5	41	-	I/O	TTL	GPIO port F bit 5.
PG0	19	-	I/O	TTL	GPIO port G bit 0.
PG1	18	-	I/O	TTL	GPIO port G bit 1.
PG7	36	-	I/O	TTL	GPIO port G bit 7.
PH0	86	-	I/O	TTL	GPIO port H bit 0.
PH1	85	-	I/O	TTL	GPIO port H bit 1.
PH2	84	-	I/O	TTL	GPIO port H bit 2.
PH3	83	-	I/O	TTL	GPIO port H bit 3.
PH4	76	-	I/O	TTL	GPIO port H bit 4.
PH5	63	-	I/O	TTL	GPIO port H bit 5.
PH6	62	-	I/O	TTL	GPIO port H bit 6.
PH7	15	-	I/O	TTL	GPIO port H bit 7.
PJ0	14	-	I/O	TTL	GPIO port J bit 0.
PJ1	87	-	I/O	TTL	GPIO port J bit 1.
PJ2	39	-	I/O	TTL	GPIO port J bit 2.
PJ3	50	-	I/O	TTL	GPIO port J bit 3.

PWM7	23 31 36	PC6 (4) PA5 (4) PG7 (4)	O	TTL	PWM 7.
PhA0	11 25 95	PD1 (3) PC4 (2) PE2 (4)	I	TTL	QE1 module 0 phase A.
PhA1	96	PE3 (3)	I	TTL	QE1 module 1 phase A.
PhB0	22 23 47 83 96	PC7 (2) PC6 (2) PF0 (2) PH3 (1) PE3 (4)	I	TTL	QE1 module 0 phase B.
PhB1	11 36 95	PD1 (11) PG7 (1) PE2 (3)	I	TTL	QE1 module 1 phase B.
RST	64	-	I	TTL	System reset input.
RXIN	37	-	I	Analog	RXIN of the Ethernet PHY.
RXIP	40	-	I	Analog	RXIP of the Ethernet PHY.
SSI0Clk	28	PA2 (1)	I/O	TTL	SSI module 0 clock.
SSI0Fss	29	PA3 (1)	I/O	TTL	SSI module 0 frame.
SSI0Rx	30	PA4 (1)	I	TTL	SSI module 0 receive.
SSI0Tx	31	PA5 (1)	O	TTL	SSI module 0 transmit.

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description
SSI1Clk	60 74 76	PF2 (9) PE0 (2) PH4 (11)	I/O	TTL	SSI module 1 clock.
SSI1Fss	59 63 75	PF3 (9) PH5 (11) PE1 (2)	I/O	TTL	SSI module 1 frame.
SSI1Rx	42 62 95	PF4 (9) PH6 (11) PE2 (2)	I	TTL	SSI module 1 receive.
SSI1Tx	15 41 96	PH7 (11) PF5 (9) PE3 (2)	O	TTL	SSI module 1 transmit.
SWCLK	80	PC0 (3)	I	TTL	JTAG/SWD CLK.
SWDIO	79	PC1 (3)	I/O	TTL	JTAG TMS and SWDIO.
SWO	77	PC3 (3)	O	TTL	JTAG TDO and SWO.
TCK	80	PC0 (3)	I	TTL	JTAG/SWD CLK.
TDI	78	PC2 (3)	I	TTL	JTAG TDI.
TDO	77	PC3 (3)	O	TTL	JTAG TDO and SWO.
TMS	79	PC1 (3)	I	TTL	JTAG TMS and SWDIO.
TXON	46	-	O	TTL	TXON of the Ethernet PHY.
TXOP	43	-	O	TTL	TXOP of the Ethernet PHY.
U0Rx	26	PA0 (1)	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
U0Tx	27	PA1 (1)	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
U1CTS	2 10 34 50	PE6 (9) PD0 (9) PA6 (9) PJ3 (9)	I	TTL	UART module 1 Clear To Send modem status input signal.
U1DCD	1 11 35 52	PE7 (9) PD1 (9) PA7 (9) PJ4 (9)	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
U1DSR	47 53	PF0 (9) PJ5 (9)	I	TTL	UART module 1 Data Set Ready modem output control line.
U1DTR	55 100	PJ7 (9) PD7 (9)	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
U1RI	97	PD4 (9)	I	TTL	UART module 1 Ring Indicator modem status input signal.
U1RTS	54 61	PJ6 (9) PF1 (9)	O	TTL	UART module 1 Request to Send modem output control line.
U1Rx	10 12 23 26 66 92	PD0 (5) PD2 (1) PC6 (5) PA0 (9) PB0 (5) PB4 (7)	I	TTL	UART module 1 receive.

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description
U1Tx	11 13 22 27 67 91	PD1 (5) PB3 (1) PC7 (5) PA1 (9) PB1 (5) PB5 (7)	O	TTL	UART module 1 transmit.
U2Rx	10 19 92 98	PD0 (4) PG0 (1) PB4 (4) PD5 (9)	I	TTL	UART module 2 receive.
U2Tx	6 11 18 99	PE4 (5) PD1 (4) PG1 (1) PD6 (9)	O	TTL	UART module 2 transmit.
USB0DM	70	-	I/O	Analog	Bidirectional differential data pin (D- per USB specification).
USB0DP	71	-	I/O	Analog	Bidirectional differential data pin (D+ per USB specification).
USB0EPEN	19 24 34 72 83	PG0 (7) PC5 (6) PA6 (8) PB2 (8) PH3 (4)	O	TTL	Used in Host mode to control an external power source to supply power to the USB bus.
USB0ID	66	-	I	Analog	This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is an A device and not pulled down is a B device).
USB0PFLT	22 23 35 65 74 76 87	PC7 (6) PC6 (7) PA7 (8) PB3 (8) PE0 (9) PH4 (4) PJ1 (9)	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.
USB0RBIAS	73	-	O	Analog	9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.
USB0VBUS	67	-	I/O	Analog	This signal is used during the session negotiation protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.
VDD	8 20 32 44 56 68 81 93	-	-	Power	Positive supply for I/O and some logic.
VDDA	3	-	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.
VDDC	38 88	-	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.

Pin Name	Pin Number	Pin Mux	Pin Type	Buffer Type <sup>a</sup>	Description
VREFA	90	-	I	Analog	This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AIN <sub>n</sub> signal is converted to 1023. The VREFA input is limited to the range specified in Table 27-2 on page 993.
XTALNPHY	17	-	I	Analog	XTALN of the Ethernet PHY.
XTALPPHY	16	-	O	Analog	XTALP of the Ethernet PHY.

a. The TTL designation indicates the pin is TTL-compatible.

**Table 25-4. Signals by Function, Except for GPIO**

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
ADC	AIN0	1	I	Analog	ADC 0 input.
	AIN1	2	I	Analog	ADC 1 input.
	AIN2	5	I	Analog	ADC 2 input.
	AIN3	6	I	Analog	ADC 3 input.
	AIN4	100	I	Analog	ADC 4 input.
	AIN5	99	I	Analog	ADC 5 input.
	AIN6	98	I	Analog	ADC 6 input.
	AIN7	97	I	Analog	ADC 7 input.
	AIN8	96	I	Analog	ADC 8 input.
	AIN9	95	I	Analog	ADC 9 input.
	AIN10	92	I	Analog	ADC 10 input.
	AIN11	91	I	Analog	ADC 11 input.
	AIN12	13	I	Analog	ADC 12 input.
	AIN13	12	I	Analog	ADC 13 input.
	AIN14	11	I	Analog	ADC 14 input.
	AIN15	10	I	Analog	ADC 15 input.
	VREFA	90	I	Analog	This input provides a reference voltage used to specify the input voltage at which the ADC converts to a maximum value. In other words, the voltage that is applied to VREFA is the voltage with which an AIN <sub>n</sub> signal is converted to 1023. The VREFA input is limited to the range specified in Table 27-2 on page 993.

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
Analog Comparators	C0+	90	I	Analog	Analog comparator 0 positive input.
	C0-	92	I	Analog	Analog comparator 0 negative input.
	C0o	24 42 90 91 100	O	TTL	Analog comparator 0 output.
	C1+	24	I	Analog	Analog comparator 1 positive input.
	C1-	91	I	Analog	Analog comparator 1 negative input.
	C1o	2 22 24 41 84	O	TTL	Analog comparator 1 output.
	C2+	23	I	Analog	Analog comparator 2 positive input.
	C2-	22	I	Analog	Analog comparator 2 negative input.
	C2o	1 23	O	TTL	Analog comparator 2 output.
	Controller Area Network	CAN0Rx	10 30 34 92	I	TTL
CAN0Tx		11 31 35 91	O	TTL	CAN module 0 transmit.
CAN1Rx		47	I	TTL	CAN module 1 receive.
CAN1Tx		61	O	TTL	CAN module 1 transmit.
Ethernet PHY	ERBIAS	33	O	Analog	9.1-kΩ resistor (1% precision) used internally for Ethernet PHY.
	LED0	59	O	TTL	MII LED 0.
	LED1	60	O	TTL	MII LED 1.
	MDIO	58	I/O	OD	MDIO of the Ethernet PHY.
	RXIN	37	I	Analog	RXIN of the Ethernet PHY.
	RXIP	40	I	Analog	RXIP of the Ethernet PHY.
	TXON	46	O	TTL	TXON of the Ethernet PHY.
	TXOP	43	O	TTL	TXOP of the Ethernet PHY.
	XTALNPHY	17	I	Analog	XTALN of the Ethernet PHY.
XTALPPHY	16	O	Analog	XTALP of the Ethernet PHY.	

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
Power	GND	9 21 45 57 69 82 94	-	Power	Ground reference for logic and I/O pins.
	GNDA	4	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
	LDO	7	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 $\mu$ F or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDDC pins at the board level in addition to the decoupling capacitor(s).
	VDD	8 20 32 44 56 68 81 93	-	Power	Positive supply for I/O and some logic.
	VDDA	3	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.
	VDDC	38 88	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
QEI	IDX0	10 72 90 92 100	I	TTL	QEI module 0 index.
	IDX1	61 84	I	TTL	QEI module 1 index.
	PhA0	11 25 95	I	TTL	QEI module 0 phase A.
	PhA1	96	I	TTL	QEI module 1 phase A.
	PhB0	22 23 47 83 96	I	TTL	QEI module 0 phase B.
	PhB1	11 36 95	I	TTL	QEI module 1 phase B.

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
SSI	SSI0Clk	28	I/O	TTL	SSI module 0 clock.
	SSI0Fss	29	I/O	TTL	SSI module 0 frame.
	SSI0Rx	30	I	TTL	SSI module 0 receive.
	SSI0Tx	31	O	TTL	SSI module 0 transmit.
	SSI1Clk	60 74 76	I/O	TTL	SSI module 1 clock.
	SSI1Fss	59 63 75	I/O	TTL	SSI module 1 frame.
	SSI1Rx	42 62 95	I	TTL	SSI module 1 receive.
	SSI1Tx	15 41 96	O	TTL	SSI module 1 transmit.
System Control & Clocks	NMI	89	I	TTL	Non-maskable interrupt.
	OSC0	48	I	Analog	Main oscillator crystal input or an external clock reference input.
	OSC1	49	O	Analog	Main oscillator crystal output.
	$\overline{\text{RST}}$	64	I	TTL	System reset input.

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
UART	U0Rx	26	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
	U0Tx	27	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
	U1CTS	2 10 34 50	I	TTL	UART module 1 Clear To Send modem status input signal.
	U1DCD	1 11 35 52	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
	U1DSR	47 53	I	TTL	UART module 1 Data Set Ready modem output control line.
	U1DTR	55 100	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
	U1RI	97	I	TTL	UART module 1 Ring Indicator modem status input signal.
	U1RTS	54 61	O	TTL	UART module 1 Request to Send modem output control line.
	U1Rx	10 12 23 26 66 92	I	TTL	UART module 1 receive.
	U1Tx	11 13 22 27 67 91	O	TTL	UART module 1 transmit.
	U2Rx	10 19 92 98	I	TTL	UART module 2 receive.
	U2Tx	6 11 18 99	O	TTL	UART module 2 transmit.

Function	Pin Name	Pin Number	Pin Type	Buffer Type <sup>a</sup>	Description
USB	USB0DM	70	I/O	Analog	Bidirectional differential data pin (D- per USB specification).
	USB0DP	71	I/O	Analog	Bidirectional differential data pin (D+ per USB specification).
	USB0EPEN	19 24 34 72 83	O	TTL	Used in Host mode to control an external power source to supply power to the USB bus.
	USB0ID	66	I	Analog	This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is an A device and not pulled down is a B device).
	USB0PFLT	22 23 35 65 74 76 87	I	TTL	Used in Host mode by an external power source to indicate an error state by that power source.
	USB0RBIAS	73	O	Analog	9.1-kΩ resistor (1% precision) used internally for USB analog circuitry.
	USB0VBUS	67	I/O	Analog	This signal is used during the session negotiation protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.

a. The TTL designation indicates the pin is TTL-compatible.

**Table 25-5. GPIO Pins and Alternate Functions**

## 26 Operating Characteristics

**Table 26-1. Temperature Characteristics**

Characteristic <sup>a</sup>	Symbol	Value	Unit
Industrial operating temperature range	$T_A$	-40 to +85	°C

a. Maximum storage temperature is 150°C.

**Table 26-2. Thermal Characteristics**

Characteristic	Symbol	Value	Unit
Thermal resistance (junction to ambient) <sup>a</sup>	$\Theta_{JA}$	34	°C/W
Average junction temperature <sup>b</sup>	$T_J$	$T_A + (P_{AVG} \cdot \Theta_{JA})$	°C

a. Junction to ambient thermal resistance  $\Theta_{JA}$  numbers are determined by a package simulator.

b. Power dissipation is a function of temperature.

**Table 26-3. ESD Absolute Maximum Ratings**

Parameter Name	Min	Nom	Max	Unit
$V_{ESDHBM}$				V
$V_{ESDCDM}$				V

## 27 Electrical Characteristics

### 27.1 DC Characteristics

#### 27.1.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device.

**Note:** The device is not guaranteed to operate properly at the maximum ratings.

**Table 27-1. Maximum Ratings**

Parameter	Parameter Name <sup>a</sup>	Value		Unit
		Min	Max	
V <sub>DD</sub>	I/O supply voltage (V <sub>DD</sub> )	0	4	V
V <sub>DDA</sub>	Analog supply voltage (V <sub>DDA</sub> )	0	4	V
V <sub>IN</sub>	Input voltage	-0.3	5.5	V
I	Maximum current per output pins	-	25	mA

a. Voltages are measured with respect to GND.

**Important:** This device contains circuitry to protect the inputs against damage due to high-static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (for example, either GND or V<sub>DD</sub>).

#### 27.1.2 Recommended DC Operating Conditions

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the V<sub>OL</sub> value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

**Table 27-2. Recommended DC Operating Conditions**

Parameter	Parameter Name	Min	Nom	Max	Unit
V <sub>DD</sub>	I/O supply voltage	3.0	3.3	3.6	V
V <sub>DDA</sub>	Analog supply voltage	3.0	3.3	3.6	V
V <sub>DDC</sub> <sup>a</sup>	Core supply voltage	1.08	1.2	1.32	V
V <sub>REFA</sub>	External voltage reference for ADC	pending <sup>b</sup>	3.0 <sup>cd</sup>	pending <sub>b</sub>	V
V <sub>IH</sub>	High-level input voltage	2.0	-	5.0	V
V <sub>IL</sub>	Low-level input voltage	-0.3	-	1.3	V
V <sub>SIH</sub>	High-level input voltage for Schmitt trigger inputs	0.8 * V <sub>DD</sub>	-	V <sub>DD</sub>	V
V <sub>SIL</sub>	Low-level input voltage for Schmitt trigger inputs	0	-	0.2 * V <sub>DD</sub>	V
V <sub>OH</sub> <sup>e</sup>	High-level output voltage	2.4	-	-	V
V <sub>OL</sub> <sup>a</sup>	Low-level output voltage	-	-	0.4	V

Parameter	Parameter Name	Min	Nom	Max	Unit
I <sub>OH</sub>	High-level source current, V <sub>OH</sub> =2.4 V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA
I <sub>OL</sub>	Low-level sink current, V <sub>OL</sub> =0.4 V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA

- a. V<sub>DDC</sub> is supplied from the output of the LDO.
- b. Pending characterization completion.
- c. Ground is always used as the reference level for the minimum conversion value.
- d. Care must be taken to supply a reference voltage of acceptable quality.
- e. V<sub>OL</sub> and V<sub>OH</sub> shift to 1.2 V when using high-current GPIOs.

### 27.1.3 On-Chip Low Drop-Out (LDO) Regulator Characteristics

Table 27-3. LDO Regulator Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
C <sub>LDO</sub>	External filter capacitor size for internal power supply	1.0	-	3.0	μF
V <sub>LDO</sub>	LDO output voltage	1.08	1.2	1.32	V

### 27.1.4 Flash Memory Characteristics

Table 27-4. Flash Memory Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
PE <sub>CYC</sub>	Number of guaranteed mass program/erase cycles before failure <sup>ab</sup>	15,000	pending <sup>c</sup>	-	cycles
T <sub>RET</sub>	Data retention at average operating temperature of 125°C	20	-	-	years
T <sub>PROG</sub>	Word program time	-	-	1	ms
T <sub>BPROG</sub>	Buffer program time	-	-	1	ms
T <sub>ERASE</sub>	Page erase time	-	-	16	ms
T <sub>ME</sub>	Mass erase time	-	-	16	ms

- a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.
- b. Caution should be used when performing block erases, as repeated block erases can shorten the number of guaranteed erase cycles.
- c. Pending characterization completion.

### 27.1.5 GPIO Module Characteristics

Table 27-5. GPIO Module DC Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
R <sub>GPIOU</sub>	GPIO internal pull-up resistor	50	-	110	kΩ
R <sub>GPIOPD</sub>	GPIO internal pull-down resistor	55	-	180	kΩ

## 27.1.6 USB Module Characteristics

The Stellaris<sup>®</sup> USB controller DC electrical specifications are compliant with the “Universal Serial Bus Specification Rev. 2.0” (full-speed and low-speed support) and the “On-The-Go Supplement to the USB 2.0 Specification Rev. 1.0”. Some components of the USB system are integrated within the LM3S9792 microcontroller and specific to the Stellaris<sup>®</sup> microcontroller design. An external component resistor is needed as specified in Table 27-6.

**Table 27-6. USB Controller DC Characteristics**

Parameter	Parameter Name	Value	Unit
R <sub>UBIAS</sub>	Value of the pull-down resistor on the USB0RBIAS pin	9.1K ± 1 %	Ω

## 27.1.7 Ethernet Controller Characteristics

**Table 27-7. Ethernet Controller DC Characteristics**

Parameter	Parameter Name	Value	Unit
R <sub>EBIAS</sub>	Value of the pull-down resistor on the ERBIAS pin	12.4K ± 1 %	Ω

## 27.1.8 Current Specifications

This section provides information on typical and maximum power consumption under various conditions.

### 27.1.8.1 Nominal and Maximum Current Specifications

The current measurements specified in the table that follows are run on the core processor using SRAM with the following specifications (except as noted):

- V<sub>DD</sub> = 3.3 V
- V<sub>DDC</sub> = 1.2 V
- V<sub>DDA</sub> = 3.3 V
- Temperature = 25°C
- Clock Source (MOSC) = 3.579545 MHz Crystal Oscillator
- Main oscillator (MOSC) = enabled
- Precision Internal oscillator (PIOSC) = disabled

**Important:** The next 2 tables should be filled in for all of the following situations:

- MOSC (from a crystal) 16 MHz, 12 MHz, 8 MHz, and 3.579545 MHz
- PIOSC SYSDIV=1, 2, 4
- MOSC (from a crystal) with PLL 100 MHz, 80 MHz, SYSDIV = 8, 64
- PIOSC with PLL 100 MHz, 80 MHz, SYSDIV = 8, 64
- 4.19 MHz HIB clock with PLL 100 MHz 80 MHz, SYSDIV = 8, 64

Table 27-8. Detailed Current Specifications

Parameter	Parameter Name	Conditions	3.3 V $V_{DD}$ , $V_{DDA}$		Unit
			Nom	Max	
$I_{DD\_RUN}$	Run mode 1 (Flash loop)	$V_{DD} = 3.3\text{ V}$ Code= while(1){} executed in Flash Peripherals = All ON System Clock = 50 MHz (with PLL)	pending <sup>a</sup>	pending <sup>a</sup>	mA
	Run mode 2 (Flash loop)	$V_{DD} = 3.3\text{ V}$ Code= while(1){} executed in Flash Peripherals = All OFF System Clock = 50 MHz (with PLL)	pending <sup>a</sup>	pending <sup>a</sup>	
	Run mode 1 (SRAM loop)	$V_{DD} = 3.3\text{ V}$ Code= while(1){} executed in SRAM Peripherals = All ON System Clock = 50 MHz (with PLL)	pending <sup>a</sup>	pending <sup>a</sup>	
	Run mode 2 (SRAM loop)	$V_{DD} = 3.3\text{ V}$ Code= while(1){} executed in SRAM Peripherals = All OFF System Clock = 50 MHz (with PLL)	pending <sup>a</sup>	pending <sup>a</sup>	
$I_{DD\_SLEEP}$	Sleep mode	$V_{DD} = 3.3\text{ V}$ Peripherals = All OFF System Clock = 50 MHz (with PLL)	pending <sup>a</sup>	pending <sup>a</sup>	mA
$I_{DD\_DEEPSLEEP}$	Deep-Sleep mode	LDO = 2.25 V Peripherals = All OFF System Clock = IOS30KHZ/64	pending <sup>a</sup>	pending <sup>a</sup>	

a. Pending characterization completion.

### 27.1.8.2 Typical Current Consumption vs. Frequency

Figure 27-1 on page 997 shows how typical current when running out of Flash memory varies with frequency. Data is provided across frequency for all peripherals on and all peripherals off. The microcontroller is clocked by MOSC using the PLL.

**Figure 27-1. Typical Current Across Frequency**

**Pending**

### **27.1.8.3 Typical Current Consumption vs. Temperature**

Figure 27-2 on page 998 shows how typical current varies across temperature when running out of Flash memory varies with frequency. Data is provided for all peripherals off. The microcontroller is clocked by MOSC using the PLL.

Figure 27-2. Typical Current Across Temperature

**Pending**

#### 27.1.8.4 Typical Peripheral Current Consumption

The current consumption of the on-chip peripherals is given in . Data is provided for the following conditions:

- I/O pins are in input mode with a static value at  $V_{DD}$  or ground and no load.
- All peripherals are not clocked except for the peripheral listed.
- Specified temperature and voltage

Table 27-9. Typical Peripheral Current Consumption

Peripheral	Current	Unit

## 27.2 AC Characteristics

### 27.2.1 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements.

Figure 27-3. Load Conditions

## 27.2.2 Clocks

The following sections provide specifications on the various clock sources and mode.

### 27.2.2.1 PLL Specifications

The following tables provide specifications for using the PLL.

Table 27-10. Phase Locked Loop (PLL) Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
$f_{\text{REF\_XTAL}}$	Crystal reference <sup>a</sup>	3.579545	-	16.384	MHz
$f_{\text{REF\_EXT}}$	External clock reference <sup>a</sup>	3.579545	-	16.384	MHz
$f_{\text{PLL}}$	PLL frequency <sup>b</sup>	-	400	-	MHz
$T_{\text{READY}}$	PLL lock time	0.562 <sup>c</sup>	-	1.38 <sup>d</sup>	ms

a. The exact value is determined by the crystal value programmed into the XTAL field of the **Run-Mode Clock Configuration (RCC)** register.

b. PLL frequency is automatically calculated by the hardware based on the XTAL field of the **RCC** register.

c. Using a 16.384-MHz crystal

d. Using 3.5795-MHz crystal

Table 27-11 on page 999 shows the actual frequency of the PLL based on the crystal frequency used (defined by the XTAL field in the **RCC** register).

Table 27-11. Actual PLL Frequency

XTAL	Crystal Frequency (MHz)	PLL Frequency (MHz)	Error
0x04	3.5795	400.904	0.0023%
0x05	3.6864	398.1312	0.0047%
0x06	4.0	400	-
0x07	4.096	401.408	0.0035%
0x08	4.9152	398.1312	0.0047%
0x09	5.0	400	-
0x0A	5.12	399.36	0.0016%
0x0B	6.0	400	-
0x0C	6.144	399.36	0.0016%
0x0D	7.3728	398.1312	0.0047%
0x0E	8.0	400	0.0047%
0x0F	8.192	398.6773333	0.0033%
0x10	10.0	400	-
0x11	12.0	400	-

XTAL	Crystal Frequency (MHz)	PLL Frequency (MHz)	Error
0x12	12.288	401.408	0.0035%
0x13	13.56	397.76	0.0056%
0x14	14.318	400.90904	0.0023%
0x15	16.0	400	-
0x16	16.384	404.1386667	0.010%

### 27.2.2.2 PIOSC Specifications

Table 27-12. PIOSC Clock Characteristics

Parameter	Parameter Name	Min	Max	Unit
f <sub>PIOSC</sub>	Internal 16-MHz precision oscillator frequency variance, factory calibrated at 25 °C <sup>a</sup>	-	±1%	-

a. Variance is ±3% across temperature.

### 27.2.2.3 Internal 30-kHz Oscillator Specifications

Table 27-13. 30-kHz Clock Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
f <sub>IOSC30KHZ</sub>	Internal 30-KHz oscillator frequency	15	30	45	KHz

### 27.2.2.4 Main Oscillator Specifications

Table 27-14. Main Oscillator Clock Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
f <sub>MOSC</sub>	Main oscillator frequency	1	-	16.384	MHz
t <sub>MOSC_PER</sub>	Main oscillator period	61	-	1000	ns
t <sub>MOSC_SETTLE</sub>	Main oscillator settling time	17.5	-	20	ms
f <sub>REF_XTAL_BYPASS</sub>	Crystal reference using the main oscillator (PLL in BYPASS mode) <sup>a</sup>	1	-	16.384	MHz
f <sub>REF_EXT_BYPASS</sub>	External clock reference (PLL in BYPASS mode) <sup>a</sup>	0	-	80	MHz

a. The ADC must be clocked from the PLL or directly from a 14-MHz to 18-MHz clock source to operate properly.

Table 27-15. MOSC Oscillator Input Characteristics

Name	Value						Condition
Frequency	16	12	8	6	4	3.5	MHz
Frequency tolerance	±100	±100	±100	±100	±100	±100	PPM
Oscillation mode	parallel	parallel	parallel	parallel	parallel	parallel	-
Equivalent series resistance (max)	70	90	120	160	200	220	Ω
Load capacitance	16	16	16	16	16	16	pF
Drive level (typ)	100	100	100	100	100	100	μw

### 27.2.3 JTAG and Boundary Scan

Table 27-16. JTAG Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
J1	$f_{TCK}$	TCK operational clock frequency	0	-	10	MHz
J2	$t_{TCK}$	TCK operational clock period	100	-	-	ns
J3	$t_{TCK\_LOW}$	TCK clock Low time	-	$t_{TCK}$	-	ns
J4	$t_{TCK\_HIGH}$	TCK clock High time	-	$t_{TCK}$	-	ns
J5	$t_{TCK\_R}$	TCK rise time	pending <sup>a</sup>	-	pending <sup>a</sup>	ns
J6	$t_{TCK\_F}$	TCK fall time	pending <sup>a</sup>	-	pending <sup>a</sup>	ns
J7	$t_{TMS\_SU}$	TMS setup time to TCK rise	20	-	-	ns
J8	$t_{TMS\_HLD}$	TMS hold time from TCK rise	20	-	-	ns
J9	$t_{TDI\_SU}$	TDI setup time to TCK rise	25	-	-	ns
J10	$t_{TDI\_HLD}$	TDI hold time from TCK rise	25	-	-	ns
J11 $t_{TDO\_ZDV}$	TCK fall to Data Valid from High-Z	2-mA drive	-	23	35	ns
		4-mA drive		15	26	ns
		8-mA drive		14	25	ns
		8-mA drive with slew rate control		18	29	ns
J12 $t_{TDO\_DV}$	TCK fall to Data Valid from Data Valid	2-mA drive	-	21	35	ns
		4-mA drive		14	25	ns
		8-mA drive		13	24	ns
		8-mA drive with slew rate control		18	28	ns
J13 $t_{TDO\_DVZ}$	TCK fall to High-Z from Data Valid	2-mA drive	-	9	11	ns
		4-mA drive		7	9	ns
		8-mA drive		6	8	ns
		8-mA drive with slew rate control		7	9	ns

a. Pending characterization completion.

### 27.2.5 General-Purpose I/O (GPIO)

**Note:** All GPIOs are 5-V tolerant.

Table 27-18. GPIO Characteristics

Parameter	Parameter Name	Condition	Min	Nom	Max	Unit
$t_{GPIO\text{R}}$	GPIO Rise Time (from 20% to 80% of $V_{DD}$ )	2-mA drive	-	14	20	ns
		4-mA drive		7	10	ns
		8-mA drive		4	5	ns
		8-mA drive with slew rate control		6	8	ns
$t_{GPIO\text{F}}$	GPIO Fall Time (from 80% to 20% of $V_{DD}$ )	2-mA drive	-	14	21	ns
		4-mA drive		7	11	ns
		8-mA drive		4	6	ns
		8-mA drive with slew rate control		6	8	ns

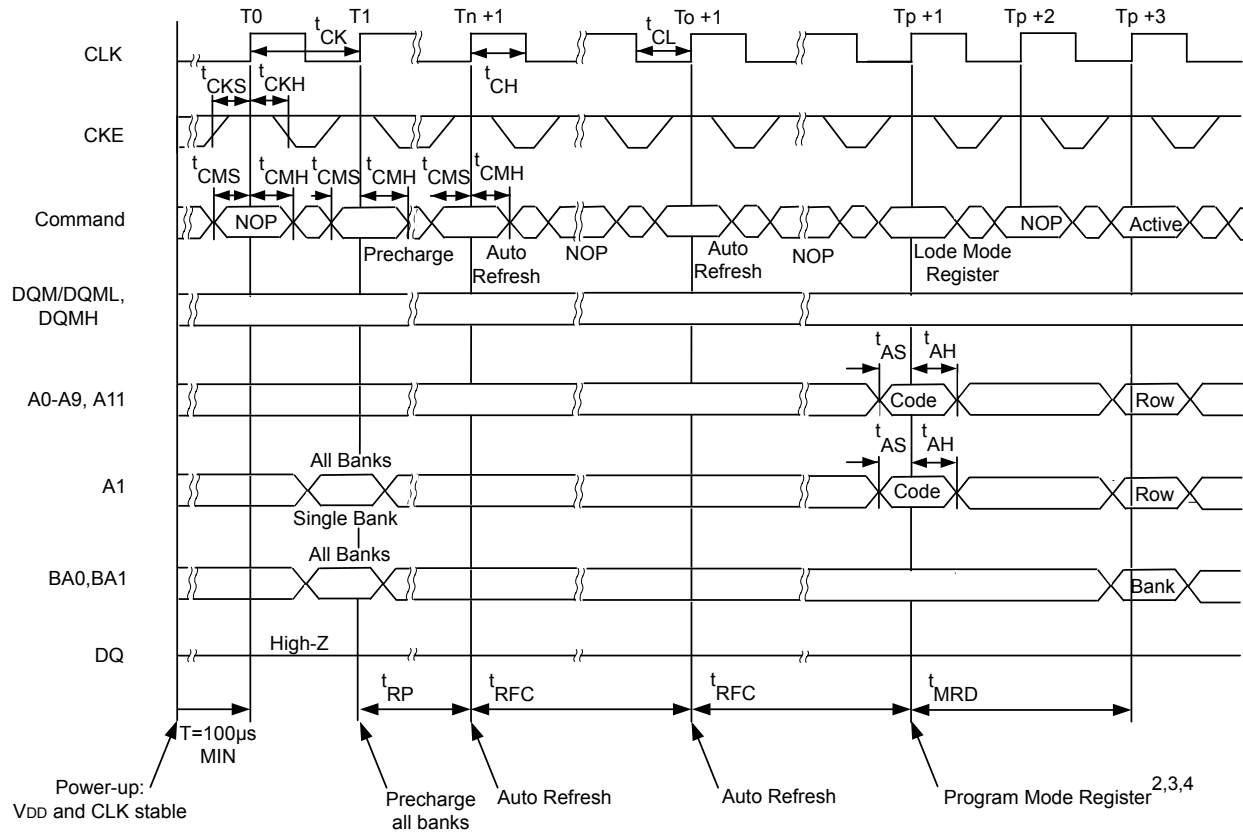

### 27.2.6 External Peripheral Interface (EPI)

Table 27-19. EPI Characteristics<sup>a</sup>

Parameter	Parameter Name	Condition	Min	Nom	Max	Unit
$t_{EPI\text{R}}$	EPI Rise Time (from 20% to 80% of $V_{DD}$ )	2-mA drive	-	3.3	4.4	ns
		4-mA drive		1.6	2.3	ns
		8-mA drive		1.1	1.5	ns
		8-mA drive with slew rate control		2.6	3.0	ns
$t_{EPI\text{F}}$	EPI Fall Time (from 80% to 20% of $V_{DD}$ )	2-mA drive	-	3.1	4.8	ns
		4-mA drive		1.8	2.7	ns
		8-mA drive		1.5	2.3	ns
		8-mA drive with slew rate control		2.3	3.4	ns

a. Load conditions when using EPI:  $C_L$  is 8 pF.

Figure 27-12. SDRAM Initialization and Load Mode Register Timing

Notes:

1. If CS is high at clock high time, all applied commands are NOP.
2. The **Mode** register may be loaded prior to the auto refresh cycles if desired.
3. JEDEC and PC100 specify three clocks.
4. Outputs are guaranteed High-Z after command is issued.

## A Boot Loader

### A.1 Boot Loader

The Stellaris<sup>®</sup> Boot Loader is executed from the ROM when flash is empty and is used to download code to the flash memory of a device without the use of a debug interface. The boot loader uses a simple packet interface to provide synchronous communication with the device. The boot loader runs off the internal oscillator and does not enable the PLL, so its speed is determined by the speed of the internal oscillator. The following serial interfaces can be used:

- UART0
- SSI0
- I<sup>2</sup>C0
- Ethernet

For simplicity, both the data format and communication protocol are identical for all serial interfaces.

See the *Stellaris<sup>®</sup> Boot Loader User's Guide* for information on the boot loader software.

### A.2 Interfaces

Once communication with the boot loader is established via one of the serial interfaces, that interface is used until the boot loader is reset or new code takes over. For example, once you start communicating using the SSI port, communications with the boot loader via the UART are disabled until the device is reset.

#### A.2.1 UART

The Universal Asynchronous Receivers/Transmitters (UART) communication uses a fixed serial format of 8 bits of data, no parity, and 1 stop bit. The baud rate used for communication is automatically detected by the boot loader and can be any valid baud rate supported by the host and the device. The auto detection sequence requires that the baud rate should be no more than 1/32 the internal oscillator frequency of the board that is running the boot loader (which is at least 8.4 MHz, providing support for up to 262,500 baud). This is actually the same as the hardware limitation for the maximum baud rate for any UART on a Stellaris<sup>®</sup> device which is calculated as follows:

$$\text{Max Baud Rate} = \text{System Clock Frequency} / 16$$

In order to determine the baud rate, the boot loader needs to determine the relationship between the internal oscillator and the baud rate. This is enough information for the boot loader to configure its UART to the same baud rate as the host. This automatic baud-rate detection allows the host to use any valid baud rate that it wants to communicate with the device.

The method used to perform this automatic synchronization relies on the host sending the boot loader two bytes that are both 0x55. This generates a series of pulses to the boot loader that it can use to calculate the ratios needed to program the UART to match the host's baud rate. After the host sends the pattern, it attempts to read back one byte of data from the UART. The boot loader returns the value of 0xCC to indicate successful detection of the baud rate. If this byte is not received after at least twice the time required to transfer the two bytes, the host can resend another pattern of 0x55, 0x55, and wait for the 0xCC byte again until the boot loader acknowledges that it has received a synchronization pattern correctly. For example, the time to wait for data back from the

boot loader should be calculated as at least  $2 \times (20(\text{bits}/\text{sync})/\text{baud rate} (\text{bits}/\text{sec}))$ . For a baud rate of 115200, this time is  $2 \times (20/115200)$  or 0.35 ms.

## A.2.2 SSI

The Synchronous Serial Interface (SSI) port also uses a fixed serial format for communications, with the framing defined as Motorola format with SPH set to 1 and SPO set to 1. See “Frame Formats” on page 573 in the SSI chapter for more information on formats for this transfer protocol. Like the UART, this interface has hardware requirements that limit the maximum speed that the SSI clock can run. This allows the SSI clock to be at most 1/12 the internal oscillator frequency of the board running the boot loader (which is at least 8.4 MHz, providing support for up to 700 KHz).. Since the host device is the master, the SSI on the boot loader device does not need to determine the clock as it is provided directly by the host.

## A.2.3 I<sup>2</sup>C

The Inter-Integrated Circuit (I<sup>2</sup>C) port operates in slave mode with a slave address of 0x42. The I<sup>2</sup>C port will work at both 100 KHz and 400 KHz I<sup>2</sup>C clock frequency. Since the host device is the master, the I<sup>2</sup>C on the boot loader device does not need to determine the clock as it is provided directly by the host.

## A.2.4 Ethernet

(Pending)

## A.3 Packet Handling

All communications, with the exception of the UART auto-baud, are done via defined packets that are acknowledged (ACK) or not acknowledged (NAK) by the devices. The packets use the same format for receiving and sending packets, including the method used to acknowledge successful or unsuccessful reception of a packet.

### A.3.1 Packet Format

All packets sent and received from the device use the following byte-packed format.

```
struct
{
    unsigned char ucSize;
    unsigned char ucChecksum;
    unsigned char Data[];
};
```

ucSize	The first byte received holds the total size of the transfer including the size and checksum bytes.
ucChecksum	This holds a simple checksum of the bytes in the data buffer only. The algorithm is $\text{Data}[0] + \text{Data}[1] + \dots + \text{Data}[\text{ucSize}-3]$ .
Data	This is the raw data intended for the device, which is formatted in some form of command interface. There should be $\text{ucSize}-2$ bytes of data provided in this buffer to or from the device.

### A.3.2 Sending Packets

The actual bytes of the packet can be sent individually or all at once; the only limitation is that commands that cause flash memory access should limit the download sizes to prevent losing bytes during flash programming. This limitation is discussed further in the section that describes the boot loader command, `COMMAND_SEND_DATA` (see “`COMMAND_SEND_DATA (0x24)`” on page 1025).

Once the packet has been formatted correctly by the host, it should be sent out over the UART or SSI interface. Then the host should poll the UART or SSI interface for the first non-zero data returned from the device. The first non-zero byte will either be an ACK (0xCC) or a NAK (0x33) byte from the device indicating the packet was received successfully (ACK) or unsuccessfully (NAK). This does not indicate that the actual contents of the command issued in the data portion of the packet were valid, just that the packet was received correctly.

### A.3.3 Receiving Packets

The boot loader sends a packet of data in the same format that it receives a packet. The boot loader may transfer leading zero data before the first actual byte of data is sent out. The first non-zero byte is the size of the packet followed by a checksum byte, and finally followed by the data itself. There is no break in the data after the first non-zero byte is sent from the boot loader. Once the device communicating with the boot loader receives all the bytes, it must either ACK or NAK the packet to indicate that the transmission was successful. The appropriate response after sending a NAK to the boot loader is to resend the command that failed and request the data again. If needed, the host may send leading zeros before sending down the ACK/NAK signal to the boot loader, as the boot loader only accepts the first non-zero data as a valid response. This zero padding is needed by the SSI interface in order to receive data to or from the boot loader.

## A.4 Commands

The next section defines the list of commands that can be sent to the boot loader. The first byte of the data should always be one of the defined commands, followed by data or parameters as determined by the command that is sent.

### A.4.1 `COMMAND_PING (0x20)`

This command simply accepts the command and sets the global status to success. The format of the packet is as follows:

```
Byte[0] = 0x03;  
Byte[1] = checksum(Byte[2]);  
Byte[2] = COMMAND_PING;
```

The ping command has 3 bytes and the value for `COMMAND_PING` is 0x20 and the checksum of one byte is that same byte, making `Byte[1]` also 0x20. Since the ping command has no real return status, the receipt of an ACK can be interpreted as a successful ping to the boot loader.

### A.4.2 `COMMAND_DOWNLOAD (0x21)`

This command is sent to the boot loader to indicate where to store data and how many bytes will be sent by the `COMMAND_SEND_DATA` commands that follow. The command consists of two 32-bit values that are both transferred MSB first. The first 32-bit value is the address to start programming data into, while the second is the 32-bit size of the data that will be sent. This command also triggers an erase of the full area to be programmed so this command takes longer than other commands. This results in a longer time to receive the ACK/NAK back from the board. This command should

be followed by a `COMMAND_GET_STATUS` to ensure that the Program Address and Program size are valid for the device running the boot loader.

The format of the packet to send this command is as follows:

```
Byte[0] = 11
Byte[1] = checksum(Bytes[2:10])
Byte[2] = COMMAND_DOWNLOAD
Byte[3] = Program Address [31:24]
Byte[4] = Program Address [23:16]
Byte[5] = Program Address [15:8]
Byte[6] = Program Address [7:0]
Byte[7] = Program Size [31:24]
Byte[8] = Program Size [23:16]
Byte[9] = Program Size [15:8]
Byte[10] = Program Size [7:0]
```

#### A.4.3 **COMMAND\_RUN (0x22)**

This command is used to tell the boot loader to execute from the address passed as the parameter in this command. This command consists of a single 32-bit value that is interpreted as the address to execute. The 32-bit value is transmitted MSB first and the boot loader responds with an ACK signal back to the host device before actually executing the code at the given address. This allows the host to know that the command was received successfully and the code is now running.

```
Byte[0] = 7
Byte[1] = checksum(Bytes[2:6])
Byte[2] = COMMAND_RUN
Byte[3] = Execute Address[31:24]
Byte[4] = Execute Address[23:16]
Byte[5] = Execute Address[15:8]
Byte[6] = Execute Address[7:0]
```

#### A.4.4 **COMMAND\_GET\_STATUS (0x23)**

This command returns the status of the last command that was issued. Typically, this command should be sent after every command to ensure that the previous command was successful or to properly respond to a failure. The command requires one byte in the data of the packet and should be followed by reading a packet with one byte of data that contains a status code. The last step is to ACK or NAK the received data so the boot loader knows that the data has been read.

```
Byte[0] = 0x03
Byte[1] = checksum(Byte[2])
Byte[2] = COMMAND_GET_STATUS
```

#### A.4.5 **COMMAND\_SEND\_DATA (0x24)**

This command should only follow a `COMMAND_DOWNLOAD` command or another `COMMAND_SEND_DATA` command if more data is needed. Consecutive send data commands automatically increment address and continue programming from the previous location. For packets which do not contain the final portion of the downloaded data, a multiple of four bytes should always be transferred. The command terminates programming once the number of bytes indicated by the `COMMAND_DOWNLOAD` command has been received. Each time this function is called it should be followed by a `COMMAND_GET_STATUS` to ensure that the data was successfully programmed into the flash. If the boot loader sends a NAK to this command, the boot loader does not increment the

current address to allow retransmission of the previous data. The following example shows a `COMMAND_SEND_DATA` packet with 8 bytes of packet data:

```
Byte[0] = 11  
Byte[1] = checksum(Bytes[2:10])  
Byte[2] = COMMAND_SEND_DATA  
Byte[3] = Data[0]  
Byte[4] = Data[1]  
Byte[5] = Data[2]  
Byte[6] = Data[3]  
Byte[7] = Data[4]  
Byte[8] = Data[5]  
Byte[9] = Data[6]  
Byte[10] = Data[7]
```

#### **A.4.6 COMMAND\_RESET (0x25)**

This command is used to tell the boot loader device to reset. Unlike the `COMMAND_RUN` command, this allows the initial stack pointer to be read by the hardware and set up for the new code. It can also be used to reset the boot loader if a critical error occurs and the host device wants to restart communication with the boot loader.

```
Byte[0] = 3  
Byte[1] = checksum(Byte[2])  
Byte[2] = COMMAND_RESET
```

The boot loader responds with an ACK signal back to the host device before actually executing the software reset to the device running the boot loader. This allows the host to know that the command was received successfully and the part will be reset.

## B ROM DriverLib Functions

### B.1 DriverLib Functions Included in the Integrated ROM

The Stellaris<sup>®</sup> Peripheral Driver Library (DriverLib) APIs that are available in the integrated ROM of the Stellaris<sup>®</sup> family of devices are listed below. The detailed description of each function is available in the *Stellaris<sup>®</sup> ROM User's Guide*.

```
ROM_ADCHardwareOversampleConfigure
    // Configures the hardware oversampling factor of the ADC.

ROM_ADCIntClear
    // Clears sample sequence interrupt source.

ROM_ADCIntDisable
    // Disables a sample sequence interrupt.

ROM_ADCIntEnable
    // Enables a sample sequence interrupt.

ROM_ADCIntStatus
    // Gets the current interrupt status.

ROM_ADCProcessorTrigger
    // Causes a processor trigger for a sample sequence.

ROM_ADCSequenceConfigure
    // Configures the trigger source and priority of a sample sequence.

ROM_ADCSequenceDataGet
    // Gets the captured data for a sample sequence.

ROM_ADCSequenceDisable
    // Disables a sample sequence.

ROM_ADCSequenceEnable
    // Enables a sample sequence.

ROM_ADCSequenceOverflow
    // Determines if a sample sequence overflow occurred.

ROM_ADCSequenceOverflowClear
    // Clears the overflow condition on a sample sequence.

ROM_ADCSequenceStepConfigure
    // Configure a step of the sample sequencer.

ROM_ADCSequenceUnderflow
    // Determines if a sample sequence underflow occurred.

ROM_ADCSequenceUnderflowClear
    // Clears the underflow condition on a sample sequence.
```

ROM\_CANBitTimingGet  
// Reads the current settings for the CAN controller bit timing.

ROM\_CANBitTimingSet  
// Configures the CAN controller bit timing.

ROM\_CANDisable  
// Disables the CAN controller.

ROM\_CANEnable  
// Enables the CAN controller.

ROM\_CANErrCntGet  
// Reads the CAN controller error counter register.

ROM\_CANInit  
// Initializes the CAN controller after reset.

ROM\_CANIntClear  
// Clears a CAN interrupt source.

ROM\_CANIntDisable  
// Disables individual CAN controller interrupt sources.

ROM\_CANIntEnable  
// Enables individual CAN controller interrupt sources.

ROM\_CANIntStatus  
// Returns the current CAN controller interrupt status.

ROM\_CANMessageClear  
// Clears a message object so that it is no longer used.

ROM\_CANMessageGet  
// Reads a CAN message from one of the message object buffers.

ROM\_CANMessageSet  
// Configures a message object in the CAN controller.

ROM\_CANRetryGet  
// Returns the current setting for automatic retransmission.

ROM\_CANRetrySet  
// Sets the CAN controller automatic retransmission behavior.

ROM\_CANStatusGet  
// Reads one of the controller status registers.

ROM\_ComparatorConfigure  
// Configures a comparator.

ROM\_ComparatorIntClear  
// Clears a comparator interrupt.

```
ROM_ComparatorIntDisable
    // Disables the comparator interrupt.

ROM_ComparatorIntEnable
    // Enables the comparator interrupt.

ROM_ComparatorIntStatus
    // Gets the current interrupt status.

ROM_ComparatorRefSet
    // Sets the internal reference voltage.

ROM_ComparatorValueGet
    // Gets the current comparator output value.

ROM_EthernetConfigGet
    // Gets the current configuration of the Ethernet controller.

ROM_EthernetConfigSet
    // Sets the configuration of the Ethernet controller.

ROM_EthernetDisable
    // Disables the Ethernet controller.

ROM_EthernetEnable
    // Enables the Ethernet controller for normal operation.

ROM_EthernetInitExpClk
    // Initializes the Ethernet controller for operation.

ROM_EthernetIntClear
    // Clears Ethernet interrupt sources.

ROM_EthernetIntDisable
    // Disables individual Ethernet interrupt sources.

ROM_EthernetIntEnable
    // Enables individual Ethernet interrupt sources.

ROM_EthernetIntStatus
    // Gets the current Ethernet interrupt status.

ROM_EthernetMACAddrGet
    // Gets the MAC address of the Ethernet controller.

ROM_EthernetMACAddrSet
    // Sets the MAC address of the Ethernet controller.

ROM_EthernetPacketAvail
    // Check for packet available from the Ethernet controller.

ROM_EthernetPacketGet
    // Waits for a packet from the Ethernet controller.
```

ROM\_EthernetPacketGetNonBlocking  
// Receives a packet from the Ethernet controller.

ROM\_EthernetPacketPut  
// Waits to send a packet from the Ethernet controller.

ROM\_EthernetPacketPutNonBlocking  
// Sends a packet to the Ethernet controller.

ROM\_EthernetPHYRead  
// Reads from a PHY register.

ROM\_EthernetPHYWrite  
// Writes to the PHY register.

ROM\_EthernetSpaceAvail  
// Checks for packet space available in the Ethernet controller.

ROM\_FlashErase  
// Erases a block of flash.

ROM\_FlashIntClear  
// Clears flash controller interrupt sources.

ROM\_FlashIntDisable  
// Disables individual flash controller interrupt sources.

ROM\_FlashIntEnable  
// Enables individual flash controller interrupt sources.

ROM\_FlashIntGetStatus  
// Gets the current interrupt status.

ROM\_FlashProgram  
// Programs flash.

ROM\_FlashProtectGet  
// Gets the protection setting for a block of flash.

ROM\_FlashProtectSave  
// Saves the flash protection settings.

ROM\_FlashProtectSet  
// Sets the protection setting for a block of flash.

ROM\_FlashUsecGet  
// Gets the number of processor clocks per micro-second.

ROM\_FlashUsecSet  
// Sets the number of processor clocks per micro-second.

ROM\_FlashUserGet  
// Gets the user registers.

```
ROM_FlashUserSave
    // Saves the user registers.

ROM_FlashUserSet
    // Sets the user registers.

ROM_GPIODirModeGet
    // Gets the direction and mode of a pin.

ROM_GPIODirModeSet
    // Sets the direction and mode of the specified pin(s).

ROM_GPIOIntTypeGet
    // Gets the interrupt type for a pin.

ROM_GPIOIntTypeSet
    // Sets the interrupt type for the specified pin(s).

ROM_GPIOPadConfigGet
    // Gets the pad configuration for a pin.

ROM_GPIOPadConfigSet
    // Sets the pad configuration for the specified pin(s).

ROM_GPIOPinIntClear
    // Clears the interrupt for the specified pin(s).

ROM_GPIOPinIntDisable
    // Disables interrupts for the specified pin(s).

ROM_GPIOPinIntEnable
    // Enables interrupts for the specified pin(s).

ROM_GPIOPinIntStatus
    // Gets interrupt status for the specified GPIO port.

ROM_GPIOPinRead
    // Reads the values present of the specified pin(s).

ROM_GPIOPinTypeADC
    // Configures pin(s) for use as analog-to-digital converter inputs.

ROM_GPIOPinTypeCAN
    // Configures pin(s) for use as a CAN device.

ROM_GPIOPinTypeComparator
    // Configures pin(s) for use as an analog comparator input.

ROM_GPIOPinTypeGPIOInput
    // Configures pin(s) for use as GPIO inputs.

ROM_GPIOPinTypeGPIOOutput
    // Configures pin(s) for use as GPIO outputs.
```

ROM\_GPIOPinTypeGPIOOutputOD  
// Configures pin(s) for use as GPIO open drain outputs.

ROM\_GPIOPinTypeI2C  
// Configures pin(s) for use by the I2C peripheral.

ROM\_GPIOPinTypePWM  
// Configures pin(s) for use by the PWM peripheral.

ROM\_GPIOPinTypeQEI  
// Configures pin(s) for use by the QEI peripheral.

ROM\_GPIOPinTypeSSI  
// Configures pin(s) for use by the SSI peripheral.

ROM\_GPIOPinTypeTimer  
// Configures pin(s) for use by the Timer peripheral.

ROM\_GPIOPinTypeUART  
// Configures pin(s) for use by the UART peripheral.

ROM\_GPIOPinTypeUSBDigital  
// Configures pin(s) for use by the USB peripheral.

ROM\_GPIOPinWrite  
// Writes a value to the specified pin(s).

ROM\_I2CMasterBusBusy  
// Indicates whether or not the I2C bus is busy.

ROM\_I2CMasterBusy  
// Indicates whether or not the I2C Master is busy.

ROM\_I2CMasterControl  
// Controls the state of the I2C Master module.

ROM\_I2CMasterDataGet  
// Receives a byte that has been sent to the I2C Master.

ROM\_I2CMasterDataPut  
// Transmits a byte from the I2C Master.

ROM\_I2CMasterDisable  
// Disables the I2C master block.

ROM\_I2CMasterEnable  
// Enables the I2C Master block.

ROM\_I2CMasterErr  
// Gets the error status of the I2C Master module.

ROM\_I2CMasterInitExpClk  
// Initializes the I2C Master block.

```
ROM_I2CMasterIntClear
    // Clears I2C Master interrupt sources.

ROM_I2CMasterIntDisable
    // Disables the I2C Master interrupt.

ROM_I2CMasterIntEnable
    // Enables the I2C Master interrupt.

ROM_I2CMasterIntStatus
    // Gets the current I2C Master interrupt status.

ROM_I2CMasterSlaveAddrSet
    // Sets the address that the I2C Master will place on the bus.

ROM_I2CSlaveDataGet
    // Receives a byte that has been sent to the I2C Slave.

ROM_I2CSlaveDataPut
    // Transmits a byte from the I2C Slave.

ROM_I2CSlaveDisable
    // Disables the I2C slave block.

ROM_I2CSlaveEnable
    // Enables the I2C Slave block.

ROM_I2CSlaveInit
    // Initializes the I2C Slave block.

ROM_I2CSlaveIntClear
    // Clears I2C Slave interrupt sources.

ROM_I2CSlaveIntDisable
    // Disables the I2C Slave interrupt.

ROM_I2CSlaveIntEnable
    // Enables the I2C Slave interrupt.

ROM_I2CSlaveIntStatus
    // Gets the current I2C Slave interrupt status.

ROM_I2CSlaveStatus
    // Gets the I2C Slave module status.

ROM_IntDisable
    // Disables an interrupt.

ROM_IntEnable
    // Enables an interrupt.

ROM_IntMasterDisable
    // Disables the processor interrupt.
```

ROM\_IntMasterEnable  
// Enables the processor interrupt.

ROM\_IntPriorityGet  
// Gets the priority of an interrupt.

ROM\_IntPriorityGroupingGet  
// Gets the priority grouping of the interrupt controller.

ROM\_IntPriorityGroupingSet  
// Sets the priority grouping of the interrupt controller.

ROM\_IntPrioritySet  
// Sets the priority of an interrupt.

ROM\_MPUDisable  
// Disables the MPU for use.

ROM\_MPUEnable  
// Enables and configures the MPU for use.

ROM\_MPURegionCountGet  
// Gets the count of regions supported by th MPU.

ROM\_MPURegionDisable  
// Disables a specific region.

ROM\_MPURegionEnable  
// Enables a specific region.

ROM\_MPURegionGet  
// Gets the current settings for a specific region.

ROM\_MPURegionSet  
// Sets up the access rules for a specific region.

ROM\_PWMDeadBandDisable  
// Disables the PWM dead band output.

ROM\_PWMDeadBandEnable  
// Enables the PWM dead band output, and sets the dead band delays.

ROM\_PWMFaultIntClear  
// Clears the fault interrupt for a PWM module.

ROM\_PWMFaultIntClearExt  
// Clears the fault interrupt for a PWM module.

ROM\_PWMGenConfigure  
// Configures a PWM generator.

ROM\_PWMGenDisable  
// Disables the timer/counter for a PWM generator block.

ROM\_PWMGenEnable  
// Enables the timer/counter for a PWM generator block.

ROM\_PWMGenFaultClear  
// Clears one or more latched fault triggers for a given PWM generator.

ROM\_PWMGenFaultConfigure  
// Configures the minimum fault period and fault pin senses for a given PWM generator.

ROM\_PWMGenFaultStatus  
// Returns the current state of the fault triggers for a given PWM generator.

ROM\_PWMGenFaultTriggerGet  
// Returns the set of fault triggers currently configured for a given PWM generator.

ROM\_PWMGenFaultTriggerSet  
// Configures the set of fault triggers for a given PWM generator.

ROM\_PWMGenIntClear  
// Clears the specified interrupt(s) for the specified PWM generator block.

ROM\_PWMGenIntStatus  
// Gets interrupt status for the specified PWM generator block.

ROM\_PWMGenIntTrigDisable  
// Disables interrupts for the specified PWM generator block.

ROM\_PWMGenIntTrigEnable  
// Enables interrupts and triggers for the specified PWM generator block.

ROM\_PWMGenPeriodGet  
// Gets the period of a PWM generator block.

ROM\_PWMGenPeriodSet  
// Set the period of a PWM generator.

ROM\_PWMIntDisable  
// Disables generator and fault interrupts for a PWM module.

ROM\_PWMIntEnable  
// Enables generator and fault interrupts for a PWM module.

ROM\_PWMIntStatus  
// Gets the interrupt status for a PWM module.

ROM\_PWMOutputFault  
// Specifies the state of PWM outputs in response to a fault condition.

ROM\_PWMOutputFaultLevel  
// Specifies the level of PWM outputs suppressed in response to a fault condition.

ROM\_PWMOutputInvert  
// Selects the inversion mode for PWM outputs.

ROM\_PWMOutputState  
// Enables or disables PWM outputs.

ROM\_PWMPulseWidthGet  
// Gets the pulse width of a PWM output.

ROM\_PWMPulseWidthSet  
// Sets the pulse width for the specified PWM output.

ROM\_PWMSyncTimeBase  
// Synchronizes the counters in one or multiple PWM generator blocks.

ROM\_PWMSyncUpdate  
// Synchronizes all pending updates.

ROM\_QEIConfigure  
// Configures the quadrature encoder.

ROM\_QEIDirectionGet  
// Gets the current direction of rotation.

ROM\_QEIDisable  
// Disables the quadrature encoder.

ROM\_QEIEnable  
// Enables the quadrature encoder.

ROM\_QEIErrGet  
// Gets the encoder error indicator.

ROM\_QEIntClear  
// Clears quadrature encoder interrupt sources.

ROM\_QEIntDisable  
// Disables individual quadrature encoder interrupt sources.

ROM\_QEIntEnable  
// Enables individual quadrature encoder interrupt sources.

ROM\_QEIntStatus  
// Gets the current interrupt status.

ROM\_QEIPositionGet  
// Gets the current encoder position.

ROM\_QEIPositionSet  
// Sets the current encoder position.

ROM\_QEIVelocityConfigure  
// Configures the velocity capture.

ROM\_QEIVelocityDisable  
// Disables the velocity capture.

```
ROM_QEIVelocityEnable
    // Enables the velocity capture.

ROM_QEIVelocityGet
    // Gets the current encoder speed.

ROM_SSIConfigSetExpClk
    // Configures the synchronous serial interface.

ROM_SSIDataGet
    // Gets a data element from the SSI receive FIFO.

ROM_SSIDataGetNonBlocking
    // Gets a data element from the SSI receive FIFO.

ROM_SSIDataPut
    // Puts a data element into the SSI transmit FIFO.

ROM_SSIDataPutNonBlocking
    // Puts a data element into the SSI transmit FIFO.

ROM_SSIDisable
    // Disables the synchronous serial interface.

ROM_SSIDMADisable
    // Disable SSI DMA operation.

ROM_SSIDMAEnable
    // Enable SSI DMA operation.

ROM_SSIEnable
    // Enables the synchronous serial interface.

ROM_SSIIntClear
    // Clears SSI interrupt sources.

ROM_SSIIntDisable
    // Disables individual SSI interrupt sources.

ROM_SSIIntEnable
    // Enables individual SSI interrupt sources.

ROM_SSIIntStatus
    // Gets the current interrupt status.

ROM_SysCtlADCSpeedGet
    // Gets the sample rate of the ADC.

ROM_SysCtlADCSpeedSet
    // Sets the sample rate of the ADC.

ROM_SysCtlClockGet
    // Gets the processor clock rate.
```

ROM\_SysCtlClockSet  
// Sets the clocking of the device.

ROM\_SysCtlDeepSleep  
// Puts the processor into deep-sleep mode.

ROM\_SysCtlFlashSizeGet  
// Gets the size of the flash.

ROM\_SysCtlGPIOAHBDisable  
// Disables a GPIO peripheral for access from the AHB.

ROM\_SysCtlGPIOAHBEnable  
// Enables a GPIO peripheral for access from the AHB.

ROM\_SysCtlIntClear  
// Clears system control interrupt sources.

ROM\_SysCtlIntDisable  
// Disables individual system control interrupt sources.

ROM\_SysCtlIntEnable  
// Enables individual system control interrupt sources.

ROM\_SysCtlIntStatus  
// Gets the current interrupt status.

ROM\_SysCtlLDOGet  
// Gets the output voltage of the LDO.

ROM\_SysCtlLDOSet  
// Sets the output voltage of the LDO.

ROM\_SysCtlPeripheralClockGating  
// Controls peripheral clock gating in sleep and deep-sleep mode.

ROM\_SysCtlPeripheralDeepSleepDisable  
// Disables a peripheral in deep-sleep mode.

ROM\_SysCtlPeripheralDeepSleepEnable  
// Enables a peripheral in deep-sleep mode.

ROM\_SysCtlPeripheralDisable  
// Disables a peripheral.

ROM\_SysCtlPeripheralEnable  
// Enables a peripheral.

ROM\_SysCtlPeripheralPresent  
// Determines if a peripheral is present.

ROM\_SysCtlPeripheralReset  
// Performs a software reset of a peripheral.

ROM\_SysCtlPeripheralSleepDisable  
// Disables a peripheral in sleep mode.

ROM\_SysCtlPeripheralSleepEnable  
// Enables a peripheral in sleep mode.

ROM\_SysCtlPinPresent  
// Determines if a pin is present.

ROM\_SysCtlPWMClockGet  
// Gets the current PWM clock configuration.

ROM\_SysCtlPWMClockSet  
// Sets the PWM clock configuration.

ROM\_SysCtlReset  
// Resets the device.

ROM\_SysCtlResetCauseClear  
// Clears reset reasons.

ROM\_SysCtlResetCauseGet  
// Gets the reason for a reset.

ROM\_SysCtlSleep  
// Puts the processor into sleep mode.

ROM\_SysCtlSRAMSizeGet  
// Gets the size of the SRAM.

ROM\_SysCtlUSBPLLDisable  
// Powers down the USB PLL.

ROM\_SysCtlUSBPLLEnable  
// Powers up the USB PLL.

ROM\_SysTickDisable  
// Disables the SysTick counter.

ROM\_SysTickEnable  
// Enables the SysTick counter.

ROM\_SysTickIntDisable  
// Disables the SysTick interrupt.

ROM\_SysTickIntEnable  
// Enables the SysTick interrupt.

ROM\_SysTickPeriodGet  
// Gets the period of the SysTick counter.

ROM\_SysTickPeriodSet  
// Sets the period of the SysTick counter.

ROM\_SysTickValueGet  
// Gets the current value of the SysTick counter.

ROM\_TimerConfigure  
// Configures the timer(s).

ROM\_TimerControlEvent  
// Controls the event type.

ROM\_TimerControlLevel  
// Controls the output level.

ROM\_TimerControlStall  
// Controls the stall handling.

ROM\_TimerControlTrigger  
// Enables or disables the trigger output.

ROM\_TimerDisable  
// Disables the timer(s).

ROM\_TimerEnable  
// Enables the timer(s).

ROM\_TimerIntClear  
// Clears timer interrupt sources.

ROM\_TimerIntDisable  
// Disables individual timer interrupt sources.

ROM\_TimerIntEnable  
// Enables individual timer interrupt sources.

ROM\_TimerIntStatus  
// Gets the current interrupt status.

ROM\_TimerLoadGet  
// Gets the timer load value.

ROM\_TimerLoadSet  
// Sets the timer load value.

ROM\_TimerMatchGet  
// Gets the timer match value.

ROM\_TimerMatchSet  
// Sets the timer match value.

ROM\_TimerPrescaleGet  
// Get the timer prescale value.

ROM\_TimerPrescaleSet  
// Set the timer prescale value.

```
ROM_TimerRTCDisable
    // Disable RTC counting.

ROM_TimerRTCEnable
    // Enable RTC counting.

ROM_TimerValueGet
    // Gets the current timer value.

ROM_UARTBreakCtl
    // Causes a BREAK to be sent.

ROM_UARTCharGet
    // Waits for a character from the specified port.

ROM_UARTCharGetNonBlocking
    // Receives a character from the specified port.

ROM_UARTCharPut
    // Waits to send a character from the specified port.

ROM_UARTCharPutNonBlocking
    // Sends a character to the specified port.

ROM_UARTCharsAvail
    // Determines if there are any characters in the receive FIFO.

ROM_UARTConfigGetExpClk
    // Gets the current configuration of a UART.

ROM_UARTConfigSetExpClk
    // Sets the configuration of a UART.

ROM_UARTDisable
    // Disables transmitting and receiving.

ROM_UARTDisableSIR
    // Disables SIR (IrDA) mode on the specified UART.

ROM_UARTDMADisable
    // Disable UART DMA operation.

ROM_UARTDMAEnable
    // Enable UART DMA operation.

ROM_UARTEnable
    // Enables transmitting and receiving.

ROM_UARTEnableSIR
    // Enables SIR (IrDA) mode on specified UART.

ROM_UARTFIFOLevelGet
    // Gets the FIFO level at which interrupts are generated.
```

ROM\_UARTFIFOLevelSet  
// Sets the FIFO level at which interrupts are generated.

ROM\_UARTIntClear  
// Clears UART interrupt sources.

ROM\_UARTIntDisable  
// Disables individual UART interrupt sources.

ROM\_UARTIntEnable  
// Enables individual UART interrupt sources.

ROM\_UARTIntStatus  
// Gets the current interrupt status.

ROM\_UARTParityModeGet  
// Gets the type of parity currently being used.

ROM\_UARTParityModeSet  
// Sets the type of parity.

ROM\_UARTSpaceAvail  
// Determines if there is any space in the transmit FIFO.

ROM\_uDMAChannelAttributeDisable  
// Disables attributes of a uDMA channel.

ROM\_uDMAChannelAttributeEnable  
// Enables attributes of a uDMA channel.

ROM\_uDMAChannelAttributeGet  
// Gets the enabled attributes of a uDMA channel.

ROM\_uDMAChannelControlSet  
// Sets the control parameters for a uDMA channel.

ROM\_uDMAChannelDisable  
// Disables a uDMA channel for operation.

ROM\_uDMAChannelEnable  
// Enables a uDMA channel for operation.

ROM\_uDMAChannelsEnabled  
// Checks if a uDMA channel is enabled for operation.

ROM\_uDMAChannelModeGet  
// Gets the transfer mode for a uDMA channel.

ROM\_uDMAChannelRequest  
// Requests a uDMA channel to start a transfer.

ROM\_uDMAChannelSizeGet  
// Gets the current transfer size for a uDMA channel.

```
ROM_uDMAChannelTransferSet
    // Sets the transfer parameters for a uDMA channel.

ROM_uDMAControlBaseGet
    // Gets the base address for the channel control table.

ROM_uDMAControlBaseSet
    // Sets the base address for the channel control table.

ROM_uDMADisable
    // Disables the uDMA controller for use.

ROM_uDMAEnable
    // Enables the uDMA controller for use.

ROM_uDMAErrorStatusClear
    // Clears the uDMA error interrupt.

ROM_uDMAErrorStatusGet
    // Gets the uDMA error status.

ROM_UpdateEthernet
    // Starts an update over the Ethernet interface.

ROM_UpdateI2C
    // Starts an update over the I2C0 interface.

ROM_UpdateSSI
    // Starts an update over the SSI0 interface.

ROM_UpdateUART
    // Starts an update over the UART0 interface.

ROM_USBDevAddrGet
    // Returns the current device address in device mode.

ROM_USBDevAddrSet
    // Sets the address in device mode.

ROM_USBDevConnect
    // Connects the USB controller to the bus in device mode.

ROM_USBDevDisconnect
    // Removes the USB controller from the bus in device mode.

ROM_USBDevEndpointConfig
    // Sets the configuration for an endpoint.

ROM_USBDevEndpointDataAck
    // Acknowledge that data was read from the given endpoint's FIFO in device mode.

ROM_USBDevEndpointStall
    // Stalls the specified endpoint in device mode.
```

ROM\_USBDevEndpointStallClear  
// Clears the stall condition on the specified endpoint in device mode.

ROM\_USBDevEndpointStatusClear  
// Clears the status bits in this endpoint in device mode.

ROM\_USBEndpointDataGet  
// Retrieves data from the given endpoint's FIFO.

ROM\_USBEndpointDataPut  
// Puts data into the given endpoint's FIFO.

ROM\_USBEndpointDataSend  
// Starts the transfer of data from an endpoint's FIFO.

ROM\_USBEndpointDataToggleClear  
// Sets the Data toggle on an end oint to zero.

ROM\_USBEndpointStatus  
// Returns the current status of an endpoint.

ROM\_USBFIFOAddrGet  
// Returns the absolute FIFO address for a given endpoint.

ROM\_USBFIFOConfigGet  
// Returns the FIFO configuration for an endpoint.

ROM\_USBFIFOConfigSet  
// Sets the FIFO configuration for an endpoint.

ROM\_USBFIFOFlush  
// Forces a flush of an endpoint's FIFO.

ROM\_USBFrameNumberGet  
// Get the current frame number.

ROM\_USBHostAddrGet  
// Gets the current functional device address for an endpoint.

ROM\_USBHostAddrSet  
// Sets the functional address for the device that is connected to an endpoint in host mode.

ROM\_USBHostEndpointConfig  
// Sets the base configuration for a host endpoint.

ROM\_USBHostEndpointDataAck  
// Acknowledge that data was read from the given endpoint's FIFO in host mode.

ROM\_USBHostEndpointDataToggle  
// Sets the value data toggle on an endpoint in host mode.

ROM\_USBHostEndpointStatusClear  
// Clears the status bits in this endpoint in host mode.

---

```
ROM_USBHostHubAddrGet
    // Get the current device hub address for this endpoint.

ROM_USBHostHubAddrSet
    // Set the hub address for the device that is connected to an endpoint.

ROM_USBHostPwrDisable
    // Disables the external power pin.

ROM_USBHostPwrEnable
    // Enables the external power pin.

ROM_USBHostPwrFaultConfig
    // Sets the configuration for USB power fault.

ROM_USBHostPwrFaultDisable
    // Disables power fault detection.

ROM_USBHostPwrFaultEnable
    // Enables power fault detection.

ROM_USBHostRequestIN
    // Schedules a request for an IN transaction on an endpoint in host mode.

ROM_USBHostRequestStatus
    // Issues a request for a status IN transaction on endpoint zero.

ROM_USBHostReset
    // Handles the USB bus reset condition.

ROM_USBHostResume
    // Handles the USB bus resume condition.

ROM_USBHostSpeedGet
    // Returns the current speed of the USB device connected.

ROM_USBHostSuspend
    // Puts the USB bus in a suspended state.

ROM_USBIntDisable
    // Disables the sources for USB interrupts.

ROM_USBIntEnable
    // Enables the sources for USB interrupts.

ROM_USBIntStatus
    // Returns the status of the USB interrupts.

ROM_WatchdogEnable
    // Enables the watchdog timer.

ROM_WatchdogIntClear
    // Clears the watchdog timer interrupt.
```

ROM\_WatchdogIntEnable  
// Enables the watchdog timer interrupt.

ROM\_WatchdogIntStatus  
// Gets the current watchdog timer interrupt status.

ROM\_WatchdogLock  
// Enables the watchdog timer lock mechanism.

ROM\_WatchdogLockState  
// Gets the state of the watchdog timer lock mechanism.

ROM\_WatchdogReloadGet  
// Gets the watchdog timer reload value.

ROM\_WatchdogReloadSet  
// Sets the watchdog timer reload value.

ROM\_WatchdogResetDisable  
// Disables the watchdog timer reset.

ROM\_WatchdogResetEnable  
// Enables the watchdog timer reset.

ROM\_WatchdogRunning  
// Determines if the watchdog timer is enabled.

ROM\_WatchdogStallDisable  
// Disables stalling of the watchdog timer during debug events.

ROM\_WatchdogStallEnable  
// Enables stalling of the watchdog timer during debug events.

ROM\_WatchdogUnlock  
// Disables the watchdog timer lock mechanism.

ROM\_WatchdogValueGet  
// Gets the current watchdog timer value.

## **C Advance Encryption Standard and Cyclic Redundancy Check Software in ROM**

AES and CRC software is available in the integrated ROM of the LM3S9792 microcontroller at 0x0100.5000. For more information on this software, see *Stellaris® ROM User's Guide*.

### **C.1 Advanced Encryption Standard Software**

The Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. It is a strong encryption method with reasonable performance and size. AES is fast in both hardware and software, is fairly easy to implement, and requires little memory. AES is ideal for applications that can use pre-arranged keys, such as setup during manufacturing or configuration.

### **C.2 Cyclic Redundancy Check Software**

CRC (Cyclic Redundancy Check) is a technique to validate a span of data has the same contents as when previously checked. This technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (e.g. XOR all bits) because it catches changes more readily.

## E Ordering and Contact Information

### E.1 Ordering Information

**Table E-1. Part Ordering Information**

Orderable Part Number	Description
LM3S9792-IQC80	Stellaris <sup>®</sup> LM3S9792 Microcontroller
LM3S9792-IQC80(T) <sup>a</sup>	Stellaris <sup>®</sup> LM3S9792 Microcontroller

a. T = Tape-and-reel packaging

### E.2 Kits

The Luminary Micro Stellaris<sup>®</sup> Family provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware, and comprehensive documentation including hardware design files:

[http://www.luminarymicro.com/products/reference\\_design\\_kits/](http://www.luminarymicro.com/products/reference_design_kits/)

- Evaluation Kits provide a low-cost and effective means of evaluating Stellaris<sup>®</sup> microcontrollers before purchase:

<http://www.luminarymicro.com/products/kits.html>

- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box:

[http://www.luminarymicro.com/products/development\\_kits.html](http://www.luminarymicro.com/products/development_kits.html)

See the Luminary Micro website for the latest tools available, or ask your Luminary Micro distributor.

### **E.3 Company Information**

Luminary Micro, Inc. designs, markets, and sells ARM Cortex-M3-based microcontrollers (MCUs). Austin, Texas-based Luminary Micro is the lead partner for the Cortex-M3 processor, delivering the world's first silicon implementation of the Cortex-M3 processor. Luminary Micro's introduction of the Stellaris® family of products provides 32-bit performance for the same price as current 8- and 16-bit microcontroller designs. With entry-level pricing at \$1.00 for an ARM technology-based MCU, Luminary Micro's Stellaris product line allows for standardization that eliminates future architectural upgrades or software tool changes.

Luminary Micro, Inc.  
108 Wild Basin, Suite 350  
Austin, TX 78746
